Does your CPU support virtualisation?

Here is a simple command that will confirm whether your computer's CPU supports virtualisation or not.

When you execute the following command…

```
[root@server1 ~]# egrep '(vmx|svm)' --color=always /proc/cpuinfo
```

…the output will be something like what's shown below:

```
flags           : fpu vme de pse tsc msr pae mce cx8 apic
sep mtrr pge mca cmov pat pse36 clflush mmx fxsr sse sse2
ht syscall

 nx mmxext fxsr_opt rdtscp lm 3dnowext 3dnow pni cx16
lahf_lm cmp_legacy svm extapic cr8_legacy misalignsse

flags           : fpu vme de pse tsc msr pae mce cx8 apic
sep mtrr pge mca cmov pat pse36 clflush mmx fxsr sse sse2
ht syscall

 nx mmxext fxsr_opt rdtscp lm 3dnowext 3dnow pni cx16
lahf_lm cmp_legacy svm extapic cr8_legacy misalignsse

[root@server1 ~]#
```

If nothing is displayed as an output of the command, your processor doesn't support hardware virtualisation.

Find the factors of a number

To find the prime factor of a number, use the factor command. It is available in GNU/Linux by default.

Shown below is an example to illustrate how this command works.

```
[bash]$ factor 25

25: 5 5

[bash]$ factor 10241

10241: 7 7 11 19
```

Are you worried that a hidden app is stealing your Internet bandwidth?

If you think that your Internet is too slow, or that your Internet provider app shows a lot of uploads and downloads that you are not doing knowingly, you might like to know which applications are eating up the bandwidth in your system.

Nethogs is a utility that will help you to get information on who or what is using the bandwidth. You need to install it if it's not already installed on your system. Use your distribution package manager to install it. On Ubuntu, you can install it using the following command:

```
sudo apt-get install nethogs
```

This utility shows bandwidth usage process wise, instead of per protocol or per subnet. This is what an end user like me would like to know.

So run the following command to check if any other process other than your browser is using the bandwidth:

```
sudo nethogs ppp0 <ENTER>
```

In place of *ppp0*, give the interface name that is connected to the Internet.

The output will look like what's shown below:

```
PID   USER     PROGRAM         DEV      SENT      RECEIVED

3045  myId /usr/lib/firefox/   ppp0    0.137   0.155 KB/sec

1562  root /opt/cisco/vpn/bin/vpnagentd    ppp0       0.068
0.074 KB/sec

?     root     <<some IP>>:<<some other IP>>:443      0.000
0.000 KB/sec

?     root     unknown TCP              0.000  0.000 KB/sec

TOTAL                                   0.204  0.229 KB/sec
```

Share Your Linux Recipes!

The joy of using Linux is in finding ways to get around problems—take them head on, defeat them! We invite you to share your tips and tricks with us for publication in *OSFY* so that they can reach a wider audience. Your tips could be related to administration, programming, troubleshooting or general tweaking. Submit them at *www.linuxforu.com*. The sender of each published tip will get a T-shirt.
