the sky, the player, the platform and the ring that will be used for our game.

Create a new folder that we can call *ring-collector.* Move into that directory.

```
mkdir ring-collector
cd ring-collector
```

Initialise the folder using npm, and install PhaserJS again for this folder as well. It will pull all the necessary *node_modules*. Run the following commands in a terminal or at the command prompt:

```
npm init -y
npm install phaser
```

Create a folder called *assets* and extract the downloaded *assets.zip* into it. Create an *index.html* file, and add the following code into it:

```
<!doctype html>
<head>
    <title>Ring Collector</title>
     <script type="text/javascript" src="node_modules/phaser/
build/phaser.min.js"></script>
</head>
<body>

<script type="text/javascript" src="game.js">
</script>

</body>
</html>
```

In the *index.html* file, load the PhaserJS framework and our game's logic.

Now create a file called *game.js* in the same folder, and add the following code. I have also added comments for each line of code to explain what it actually does and why we are using it.

```
let game = new Phaser.Game(800, 600, Phaser.AUTO, '', {
preload: preload, create: create, update: update });
function preload() {
     //Loading assets such as background image, object image,
game sprites.
    game.load.image('sky', 'assets/sky.png');
    game.load.image('ground', 'assets/platform.png');
    game.load.image('ring', 'assets/ring.png');
    game.load.image('player', 'assets/player.png');
}

// Variables
let player;
let platforms;
let cursors;

let rings;
let points = 0;
let pointsText;

function create() {
     // Since we are building an arcade style game, we enable
arcade physics system using following function
    game.physics.startSystem(Phaser.Physics.ARCADE);

    // This function will add 'sky' asset as background to
our canvas.
    game.add.sprite(0, 0, 'sky');

    // The platforms group contains the ground and the 3
ledges we can jump on
    platforms = game.add.group();

    // Enable physics for any object that is created in this
group
    platforms.enableBody = true;

    // Here we create the ground.
    let ground = platforms.create(0, game.world.height - 64,
'ground');

    // Scale it to fit the width of the game (the original
sprite is 400x32 in size)
    ground.scale.setTo(2, 2);
    // This stops it from falling away when you jump on it
    ground.body.immovable = true;

    // Now let's create three ledges, at 3 different
locations
    let ledge = platforms.create(400, 400, 'ground');
    ledge.body.immovable = true;
    ledge = platforms.create(-150, 250, 'ground');
    ledge.body.immovable = true;

    ledge = platforms.create(400, 150, 'ground');
    ledge.body.immovable = true;

    // The player and its settings, such as height and width
    player = game.add.sprite(32, game.world.height - 150,
'player');

    // Enable physics on the player
    game.physics.arcade.enable(player);
    // Player physics properties, such as bounce and bounding
it to canvas only so it does not go off screen
    player.body.bounce.y = 0.2;
    player.body.gravity.y = 300;
    player.body.collideWorldBounds = true;
```
