Hyperledger Iroha: A Blockchain Framework *for* Mobile Apps

This article is for open source enthusiasts with an interest in blockchain technology, and continues with the series on blockchain frameworks in Project Hyperledger. So let's look at Hyperledger Iroha, see what makes it unique and learn how to get started with this framework.

Hyperledger Iroha is a blockchain framework, and one of the Hyperledger projects hosted by The Linux Foundation. Initially contributed by Soramitsu, Hitachi, NTT Dat and Colu, it is designed to be simple and easy to incorporate into infrastructure projects requiring distributed ledger technology. Hyperledger Iroha features a simple, modern construction, has a domain-driven C++ design, with an emphasis on mobile application development, and it comes with the YAC consensus algorithm. This framework is a blockchain platform implementation, designed to be easily incorporated into other distributed ledger technologies. Hyperledger Iroha is designed to compile a library of reusable modular components that enhance existing distributed ledger frameworks.

The goals of Hyperledger Iroha

The team behind Hyperledger Iroha set out to achieve the following three goals:

1. Provide an environment for C++ developers to contribute to Hyperledger.
2. Provide infrastructure for mobile and Web application support.
3. Provide a framework to introduce APIs and a new consensus algorithm that can potentially be incorporated into other frameworks in the future.

The architecture

The core architecture of Hyperledger Iroha was inspired by Hyperledger Fabric. The creators of Hyperledger Iroha have emphasised the importance of this framework in fulfilling the need for user-friendly interfaces. In doing so, they've created a framework with many defining features, and have achieved their stated goals of a simple construction, a modern C++ design with an emphasis on mobile
