blockchain deployments.
- Supports Ethereum Virtual Machine (EVM) execution and Ethereum-based smart contracts.
- Offers enterprise-grade features like privacy, permissioning, and scalability.
- Suitable for industries such as finance, supply chain, and government.

Hyperledger Indy
- Framework for decentralised identity management.
- Designed to provide individuals, organisations, and connected devices with self-sovereign identity capabilities.
- Offers features like verifiable credentials, decentralised identifiers (DIDs), and zero-knowledge proofs for privacy.
- Aimed at applications requiring secure, interoperable, and user-controlled identity solutions.

Hyperledger Aries
- Infrastructure for interoperable identity solutions.
- Complements Hyperledger Indy by providing a toolkit for building decentralised identity systems and peer-to-peer interactions.
- Offers protocols, data models, and cryptographic primitives for secure and portable identity interactions.
- Enables use cases like verifiable credentials, decentralised identifiers, and secure messaging.

Hyperledger Caliper
- Blockchain benchmarking tool for measuring the performance of blockchain platforms.
- Supports various blockchain frameworks, including Hyperledger Fabric and Sawtooth.
- Allows users to define and execute performance tests to evaluate throughput, latency, and resource utilisation.
- Useful for optimising and comparing the performance of different blockchain deployments.

Hyperledger features

Modularity: Hyperledger is designed to be modular, allowing users to select and combine components that best fit their specific use cases. This modularity enables flexibility and customisation, accommodating diverse requirements across different industries and applications.

Permissioned blockchains: Hyperledger supports permissioned blockchain networks, where participants are known and trusted. This model contrasts with permissionless blockchains like Bitcoin, which allow anyone to join the network and participate anonymously. Permissioned blockchains are suitable for enterprise use cases where privacy, scalability, and regulatory compliance are critical.

Distributed ledger technology (DLT): It provides a framework for building distributed ledger applications. Distributed ledgers maintain a shared, replicated, and synchronised database across multiple nodes, ensuring transparency, immutability, and resilience to failures or attacks.

Consensus mechanisms: Hyperledger offers pluggable consensus mechanisms, allowing network participants to choose one that best suits their requirements. Consensus mechanisms determine how transactions are validated and added to the blockchain. Hyperledger supports various consensus algorithms, including Practical Byzantine Fault Tolerance (PBFT), Raft, and Proof of Elapsed Time (PoET).
