Metaverse: Immerse Yourself in a Virtual World

The metaverse has been around for some time now, and promises to be a mainstream technology over the next few years. Many companies across the world already have a presence in it, but there still are a few challenges to overcome.

The metaverse is still evolving. Many large enterprises are exploring new business models with it including virtual training, virtual service agents, virtual touring, and virtual industrial visits, to name a few. We can expect full-fledged implementation of the metaverse in the next 7-9 years, with the crypto economy and spatial technology driving its growth.

There are three integral components of metaverse solution development.

Virtual reality (VR): This is a 360-degree immersive digital environment that simulates the real world. It requires special devices like a VR headset and head mounted devices (HMD). Examples are PS4 games, driving simulators, and network based 3D games.

Augmented reality (AR): In AR, real-world objects are enhanced by digital content and the technology can work with a regular mobile camera. However, it requires special software. Examples include Google ARCore/ Sky Map, HoloLens, and Snapchat.

Mixed reality (MR): Here, physical and digital objects co-exist. The real world and digital world merge to create an interactive experience. MR requires special displays and devices. Examples include virtual makeup applications and virtual furniture fittings.

In short, metaverse combines VR and AR along with IoT, AI, cloud and blockchain to create augmented virtual worlds, in which users immerse as avatars. It requires high-end computing and special software.

Metaverse vs multiverse

In the metaverse, humans hide their identity and travel as an avatar. All transactions, like online trading, are through cryptocurrencies on the blockchain, which is a highly secured platform for virtual shopping and trading. Multiverse is commonly used for gaming and virtual collaboration since it has multiple digital worlds like cyclic, simulated, quantum and holographic universes.
