

Amazon envisions winning Walmart and Target to open source

Last year, Amazon had created Dent, an open source organisation. Dent has the tools and technologies that facilitate Amazon in operating its Go stores. In addition to cashier-less purchasing, Go also provides automated inventory management. It works with Marvell Technology Group, an organisation dealing in technology solutions; and with Cumulus Networks, a networking software company.

According to *The Wall Street Journal*, Amazon is now looking to take along Target and Walmart. However, apparently neither company plans to play a part in this scheme right now. Amazon's plans to work together with its retail rivals on in-store technology might be for the following reasons:

- Working with retailers through Dent could allow Amazon to make its technology solutions more affordable.
- 
- Working in partnership with merchants can aid Amazon in expanding its brick-and-mortar retailer outlets. Amazon has already begun licensing its Just Walk Out technology to third-party merchants, and working with retailers through Dent could create more collaborations.
 - By introducing its solutions to more stores, Amazon could scale its technology more quickly and efficiently in the future.

then presents the suggested changes to the appropriate engineer for approval.

Piranha could turn out to be a valuable tool for organisations that have a lot of code to maintain. Automating the removal of useless code not only frees up time for developers but also theoretically enhances security by reducing a workload's attack surface.

Piranha is available on GitHub. As of now, it supports Java, Swift, and Objective-C.

Open source respirators to fight coronavirus

By the means of its 'ultimate medical hackathon', Hackaday has called upon the open source community for support in creating a blueprint for an open source respirator that could be manufactured and installed to help those suffering from coronavirus. A respirator is a gadget made to safeguard the wearer from breathing in hazardous airs, including particulate matter, airborne micro-organisms, etc.

As observed in Italy, hospitals came across obstacles when maintaining medical apparatus to provide respiratory assistance to patients. Cases have been reported of suppliers who have not been able to provide the hospital staff with valves because of the coronavirus outbreak.

A hospital in Brescia, a city in northern Italy, where the coronavirus outbreak has been the most severe, has started making use of 3D-printed valves for its 'reanimation' machines with the help of a local firm specialising in 3D-printing. Cristian Fracassi, chief executive of Isinnova, revealed that he reverse engineered and 3D-printed the valves as the usual supply chain couldn't keep up with the hospital's unexpected sudden demand. Though, according to *Business Insider*, the patent holders of the valve have threatened to sue Fracassi for copyright infringement.

There are certain breathing apparatuses that aerosolise the virus, diffusing it into the air and hence harming those around the infected. To battle this, Hackaday has specified that nasal cannula-based NIV (non-invasive ventilation) systems are required. These humidify the air, mix it with oxygen and then push a constant stream of it into the lungs of the user. If a simple working system can be designed, it will definitely give a major boost to manufacturers all over the world and have a major impact in the fight against COVID-19.
