

Payara Services launches the open source Payara Platform 5.201

Payara Services has released its latest open source platform called Payara Platform 5.201. The platform consists of five new features, 12 improvements, 21 component upgrades, and 31 bug fixes. It includes an extended and updated version of the existing monitoring console, request tracing cluster configuration, and a technical preview of the data grid encryption feature.

Steve Millidge, founder of Payara, said, "Once again the Payara team has delivered an excellent release of the Payara Platform with leading-edge security, monitoring and encryption capabilities. Payara Platform 201 is the community foundation of our Payara Enterprise product. Going forward, we will be delivering further rapid innovation in Jakarta EE and MicroProfile within the Payara Platform."

Company sources have said that Payara Platform 5.201 is the first release of 2020 and it will sync the stability and community streams. The stability stream incorporates the features that have been tested and are ready for production environments. It will form the basis of development for Payara Platform Enterprise for the coming year.

This platform comes two years after the release of the original Payara Platform 5. The company has put the Payara Platform Enterprise on a monthly release schedule for customers and a quarterly release schedule for the community.

secure transactions on public blockchains. He added that this initiative will build on work that's already been done and start filling in gaps like enterprise directories and private business logic. This will allow enterprises to run end-to-end processes like procurement with strong privacy.

The Baseline Protocol will integrate multiple technologies like zero-knowledge proofs, off-chain storage, and distributed identity. It will help enterprises to set up and synchronise processes and agreements using common standards with complete privacy and without storing sensitive business information on the blockchain.

The protocol will support smart contracts and accepted industrywide tokenisation standards. The initial release of the protocol will include the process design and key components to enable volume purchase agreements.

Linux Foundation open sources project to help in disaster relief

According to *smartcitiesworld*, the Linux Foundation will make the Project Owl IoT device's firmware open source. This will help organisations to know more about the whereabouts of people and the logistics support available, for effective disaster response. This project is a cloud based analytics tool.

The Foundation said that its open governance model will help a global network of developers to speed up the development of the mesh networks. This can help in saving lives after a natural disaster. The aim of this project is that the nodes will create large-scale communication networks following natural disasters.

As per the report, this firmware can turn a wireless device into a 'DuckLink'. This mesh network node is capable of connecting to any other 'Ducks' physically around it. First responders can also use analytics and data sources to build a dashboard and formulate an action plan. This can include coordinating resources, learning about weather patterns, and communicating with civilians.

Stordis joins open source platform, Telecom Infra Project

Open networking firm Stordis has joined the Telecom Infra Project (TIP) to help in developing open source hardware and software for future networks. TIP was founded in 2016 by telecom companies to create an open source platform for next-generation networks.
