

Cryptomator: This Cloud Encryption Tool is Simple and Easy to Use

Disk encryption is a technology that converts any data into unreadable code and stores it on a device like a hard disk. The unreadable code is decrypted using a key that converts it back to readable data. This process of encrypting and decrypting data on a storage device helps to protect sensitive data from unauthorised access. There are many disk encryption software available online, a number of which are free and open source. Cryptomator is one of them.

Cryptomator (<https://cryptomator.org/>) is disk encryption software that allows users to encrypt any data for protection, but it is different from other such software. This software can encrypt data and store it on various cloud storage networks like Dropbox and Google Drive. Cryptomator was created by a company called Skymatic GmbH (Germany) in 2016, and is licensed under GPLv3 as FOSS.

Minimum system requirements

The Cryptomator client can run on any desktop PC, laptop or smartphone. In order to use the latest version of the client software on a desktop PC or laptop, you must have one of the supported operating systems, which include Windows 7, 8 and 10; MacOS 10.11, 10.12, 10.13, 10.14 and 10.15, as well as TODO Linux. Cryptomator supports Android 4.3 and iOS 10.0 on

smartphones, and is also compatible with iPad and iPod Touch. It requires Java 9 or a newer version to run on any system properly.

Features

Listed below are some of the key features of this software.

Transparent encryption: With this type of encryption, you will not notice any difference when working with your files. Cryptomator creates a virtual hard drive, which gets synchronised with the encrypted data on cloud storage, and that data can easily be accessed using the virtual drive. You can work on this drive just as you would on a USB Flash drive, though the data will be encrypted and stored somewhere on the cloud – for example, on Google Drive.

Individual file encryption: With Cryptomator, everything you put on the virtual hard drive is encrypted individually in the vault. Compared to other disk encryption utilities, Cryptomator encrypts each file individually, and if you make any change to a file in your vault then that file is only encrypted after being changed. In this way, the synchronisation client of your cloud storage provider knows exactly what needs to be uploaded and what doesn't.

Ease of use and reliability: The simplicity and ease of use is the key
