

Q . How does the explanation change, when talking to a senior techie like a CTO?

A. At this level, it is even simpler. You have historically released software once a quarter or even once a year or more. You know that this demand has changed with the cloud, microservices and agility movements. We give you the ability to get a new version rapidly, and control where the version was validated and how it ends up in runtime, as quickly as possible. We've been doing this for more than ten years, at scale. When we started, our customers managed a gigabyte, then later a terabyte and today we have customers with petabytes of binary software creating dozens or hundreds of builds a day.

Q . You mentioned the word 'control', which a lot of developers do not like. So how would you explain JFrog's promise to them? What would your pitch be?

A. The word 'control' to developers can sound like something being imposed on them. It's 'someone else's control'. But the developer roots of JFrog demand that we provide speed and agility to developers, giving them as much control over their environments as possible, without sacrificing their speed.

Q . According to you, the drivers within the company are the developers, who then take it to DevOps, on to the CTO and finally the CEO, who signs the cheque. Is that how it works?

A. Yes. To-date, JFrog has had only an inside sales force with no outbound sales. The first time we ever talked to a company was because the developers said that they needed a

professional version of JFrog tools. Then we started the discussion with the managers and so on, up the chain. Developers – as some like our friends at RedMonk have said – are still the kingmakers.

Q . Can you explain the term 'liquid software' that's mentioned quite a few times on your website?

A. The concept of liquid software is to enable continuous, secure, seamless updates of every piece of software that is running, without any downtime. This is very different from the traditional 'build, package, distribute once a year' model. The old way doesn't scale. The new world of 'liquid software' makes the update process nearly seamless from code to end device.

Q . Has the shift to 'Everything-as-a-Service' become the main driver for this concept of liquid software?

A. Yes. People are not making Software-as-a-Service, they are delivering services. They are using our liquid software pipeline delivery process for every kind of delivery. It's important to note that 'as-a-service' isn't just for the cloud, but is in fact the standard for every type of software delivery.

Q . How is JFrog connected with open source and how does it shift to an enterprise paid version? What is the licensing model at JFrog?

A. We have an open source version licensed under AGPL. This version allows you to do a lot of Java-related work, and is sometimes where developers start to 'kick the tires'. There is also an edition specifically for C/C++ developers using the Conan framework. Since

most development shops do more than one type of development, our commercial versions – starting with a pro subscription – universally support all package types. From there on, there are other plans available that include HA, security and compliance tools, distribution and more. We have also recently added JFrog Pipelines for the full automation of pipelines across the organisation. So, you can choose what makes the most sense for your company, and JFrog can grow alongside your needs as you mature your DevOps and DevSecOps infrastructure.

Q . Do you have a different set of solutions for developers depending on whether they are working on the Web, mobile or IoT?

A. No, we are universal. You don't need to re-install different things for different technology. So, whether you are a Ruby developer or a Python developer; or if you have Docker, Debian, Microsoft or NuGet, you get everything in one single tool. Pipelines are so unique to each organisation that we need to support all of them.

Q . Are there any specific solutions or capabilities that you have developed for IoT?

A. Yes. Quite early on, we worked with customers on an IoT offering. We provided an IoT-specific solution, which is an extension of Debian for IoT, and we also have Conan and Yocto. Controlling and increasing the speed of delivery is something that is in the early stages of the IoT environment. So we are helping in this integration and providing tools that are enabling different technologies on your JFrog platform that are tailored to an IoT environment.
