

Fairwinds launches open source SaaS platform, Fairwinds Insights

According to a report in *Businesswire*, cloud-native infrastructure solutions provider, Fairwinds, has launched the open source Software-as-a-Service (SaaS) platform called Fairwinds Insights for DevOps teams that manage multiple Kubernetes clusters and require visibility into infrastructure such as preventing potential problems from occurring.

Fairwinds Insights is in public beta mode at present, and is free for any early adopter who wants to try out the software. The platform uses an extensible architecture to launch a set of open source security, reliability, and auditing tools, the report mentions. As of now, the suite comprises Fairwinds Polaris, Fairwinds Goldilocks, and Aqua Security's Kube-hunter.

The company says the platform solves problems that DevOps teams typically face, like eliminating the time-intensive process of researching, learning and deploying the available Kubernetes auditing tools. It also automatically organises and normalises data from each tool, enabling engineers to get prioritised recommendations across all clusters.

Through this platform, DevOps teams can proactively manage the handing over from development to production. The platform can integrate into deployment pipelines to identify misconfigurations and fix them before releasing to production.

The company also plans to integrate additional open source Kubernetes auditing tools to the Insights platform. Through its Integration Partnership Program, maintainers of open source will be able to integrate with Fairwinds Insights.

Rhys Arkins, founder of Renovate, said, "Renovate was developed because running user-facing applications with outdated dependencies is not a serious option for software projects today. It increases the likelihood of unfixed bugs, and increases the quantity and impact of security vulnerabilities within software applications. With Renovate, you can automatically and efficiently keep dependencies up to date, integrating this process into any DevOps workflow."

WhiteSource sources say it will continue to work on the Renovate open source project, which currently has over 5,000 commitments from more than 150 contributors. WhiteSource Renovate will be integrated into the WhiteSource product portfolio, which includes WhiteSource Core and WhiteSource for Developers.

Rami Sass, CEO of WhiteSource, said, "By incorporating all of Renovate's current commercial offerings into a free WhiteSource Renovate solution, and by maintaining the open source component, WhiteSource underscores its commitment to helping the software developer community more easily address open source management and security vulnerability challenges, so that developers can spend more time innovating and less time manually resolving security vulnerabilities or dependency updates."

GitHub launches Security Lab to protect open source projects, and Arctic Code to preserve OSS

GitHub has launched its Security Lab to protect open source code projects. It plans to bring together security researchers from partner organisations like Google, Microsoft, Mozilla, Oracle, Uber and HackerOne for this purpose. With this aim, GitHub is open sourcing various analysis software, like CodeQL from Semmle, to power the Security Lab. It acquired Semmle in September this year. GitHub claims it has used CodeQL code analysis to find over 100 vulnerabilities in open source projects. GitHub has also launched security advisories to work with maintainers in a

private space and enable the results of security research to be applied to common vulnerabilities and exposures (CVE).

According to a report by Venturebeat, GitHub also plans to open the Arctic Code Vault to store and preserve open source software like Flutter and TensorFlow. The code for all open source projects will be stored in the vault on films with frames that include 8.8 million

pixels each, which is expected to last for 1,000 years, claim sources at GitHub.

The vault is in a decommissioned coal mine in Svalbard, Norway, which is one of the northernmost cities on Earth. Archivists believe the cold and near-constant conditions in Svalbard help in preservation. The Arctic Code Vault will be extended to all public repositories in February next year as per the report.

According to the GitHub Octoverse report 2019, GitHub is used by more than 40 million developers and at present, hosts more than 100 million repositories. The GitHub Arctic Code Vault is a part of the GitHub Archive Program, which is a collaboration with groups like the Internet Archive.

The report says that the first glimpse of the public repository code will be available on February 2, 2020. Gradually, GitHub will develop capabilities to store code once a year or every two years. It will also provide ways for open source projects to retrieve code, but to enable that, work is still under progress according to GitHub CEO Nat Friedman.
