

quality collaboration experiences for the open source community at work and in educational institutions.

The company also added that most of its customers have devices running on a variety of different platforms like Windows 10, Linux and others. It added that Microsoft is dedicated to supporting mixed environments across cloud and productivity offerings.

***astTECS gets TEC certification**

*astTECS, a provider of enterprise unified communication products and services based on the Asterisk open source platform, has announced that its IP PBX E-series has got TEC certification from DoT (Department of Telecommunications), government of India. Company sources state that *astTECS is the first open source telecommunication company to get this certification.

According to the Indian Telegraph (Amendment) Rules of 2017, telecom products covered under SCS and GSC, which are being used or are capable of being used, shall have to undergo prior mandatory testing and certification in respect of the parameters as determined by DoT from time to time—from October 1, 2019.

“We are proud to announce another feather in the cap of *astTECS, the award of ‘TEC Certification’ for our PABX products. A milestone in our relentless pursuit of revolutionising the global PBX market with feature-rich, price competitive and most reliable unified communication solutions complying with all regulatory norms,” said Lt Col Shaju, general manager, *astTECS.

“With the TEC stamp of approval, customers can now install an IP PBX solution instead of having to piece together the hardware and software separately,” said Dr Devasia Kurian, managing director of *astTECS.

Rasa Technologies open sources Carbon Bot

Rasa Technologies has made Carbon Bot open source. Carbon Bot is an interactive assistant deployed on Facebook Messenger which was designed to help climate-conscious individuals planning to travel during the holiday season.

Dr Alan Nichol, co-founder and CTO of Rasa Technologies Inc., said, “More and more people are conscious of the carbon emissions caused by flying. By making consumers aware of the tons of carbon they are emitting with each flight, we hope they consider alternative travel methods and buy carbon offsets. We have open sourced the assistant and the data used to train the algorithms, so that others can extend and enhance Carbon Bot for other use cases.”

Travellers can send a message to Carbon Bot on Facebook asking for help to find carbon offsets for their flights. Carbon Bot will ask questions specific to the traveller. It will also suggest projects to donate to in exchange for UN-certified carbon offset credits. The bot can also help travellers assess their past and future travels to determine their carbon footprint and lead them to a site where they can buy offset credits.

Linux Foundation launches automated compliance tooling programme

The Linux Foundation has formed a new open source code licensing programme called Automated Compliance Tooling (ACT), which will be headed by Google, VMware and Siemens. The programme will manage the responsibility and investment challenges that open source code is facing in recent times.

As per a report by *SDxCentral*, the Linux Foundation said that using open source code comes with a responsibility to comply with the terms of the code’s licence. The goal of ACT will be to consolidate investments in this area, and enhance the interoperability and usability of open source compliance tooling.

The programme will consist of five projects. First, it will have the Linux Foundation Fossology open source licence compliance software system and toolkit. It will allow users to run licence, copyright, and export control scans from a Representational State Transfer (REST) API. It will also include the open source software (OSS) Review Toolkit (ORT). (The ORT supports automated and customisable open source compliance checks of source code and dependencies of a project.)

The project will also have a Quartermaster, which was contributed by Endocode. It will integrate into the build system to learn about the software products, their sources, and dependencies. It will also include an aspect of the existing Linux Foundation Software Package Data Exchange (SPDX) Tools project.

Finally, the project will have the VMware-developed Tern inspection tool, which has been designed to find meta data of the package installed in a container image. This will allow it to provide depth in understanding a container’s bill of materials.
