

device must be rooted. The selected state will be in effect for the chosen apps until the timer runs its course, after which the apps will toggle back to their default state.

AquaDroid

Water intake is something we just don't take seriously since we are so preoccupied with work in the office or on the road. We lose track of time and forget to drink adequate quantities of water, which is harmful to our health.

AquaDroid is a simple app that gives you notifications to drink water at regular intervals. Once installed, you will be asked the following details:

1. Your name and gender
2. Your weight in kilograms
3. Your workout period (in minutes) for the day
4. Your wake-up time and sleep time

Based on the above information, AquaDroid will determine the water intake target for you. The app's main screen will show you how much of that target you have achieved through the course of the day. Below that, you will see the various options available for you to add up to your water drinking target. For example, you may not want to drink only water through the day, and may prefer coffee, tea or milk. You can choose the drink more appropriate for your needs.

Your water intake will change depending on your weight. So if you're in the process of reducing your weight or gaining it, make sure to update your current weight in the app.

The notifications can be customised by setting your notification message, notification tone and notification frequency.

The intake report also shows you the target, as well the remaining glasses/millilitres that need to be drunk to reach the target water intake.

Go to Sleep

Sleep is very important for our body, as well as for our mental health. On an

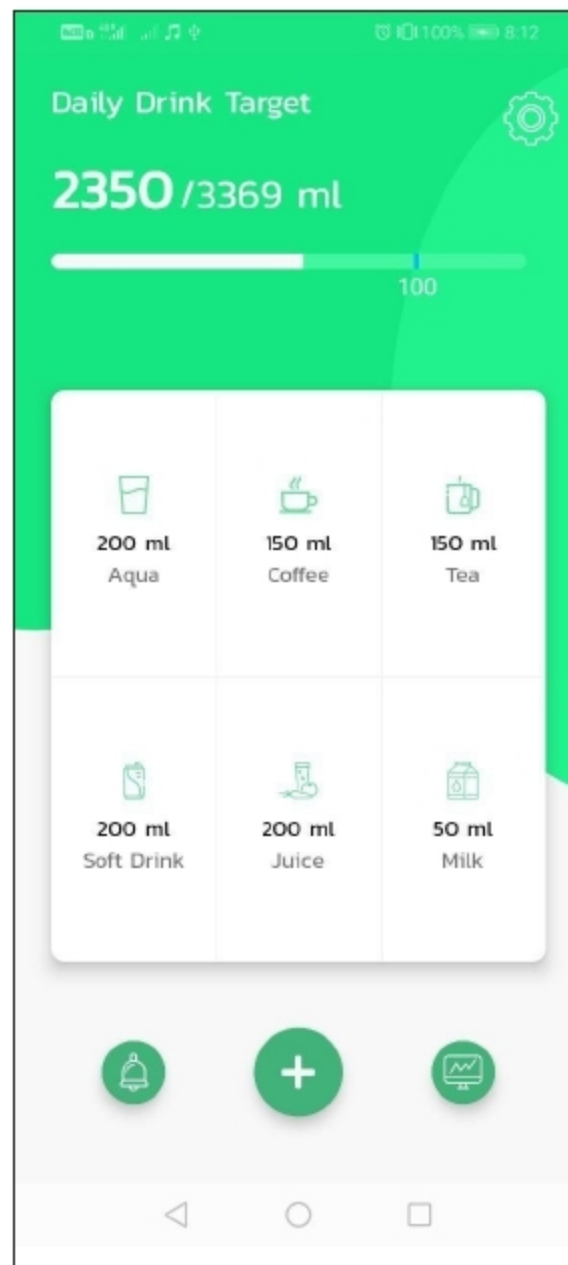

Figure 2: AquaDroid

average, we need about eight hours of sleep, but there are many factors that can disrupt your sleep cycle. Mobile devices can play a huge role in helping us work through sleep disruption because we tend to keep these devices with us at all times. Some people can lose track of time when using mobile devices, especially before bedtime.

Go to Sleep helps you to restore your sleep cycle. It prevents you from spending too much of your sleep time on mobile devices.

All you need to enter is the time at which you sleep; then, at the predefined time, the app will give a notification that it is bedtime and you need to sleep.

Sounds simple, right? But read on because the good stuff is yet to come. The main screen displays the time remaining for your bedtime, but this app can do a lot more. Just click on

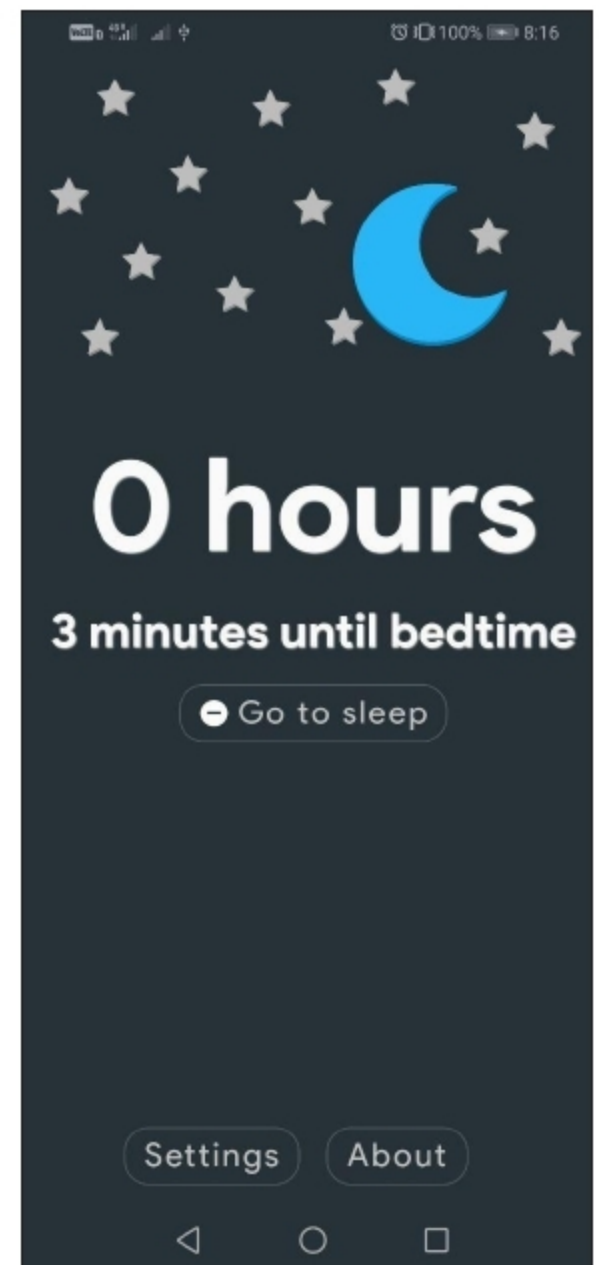

Figure 3: Go to Sleep

Settings from the main screen to get a host of customisation options, some of which I'd like to mention here.

Automatic Do Not Disturb: When you enable this option, it activates the *Do Not Disturb* mode two minutes after the last reminder for your bedtime was given.

Inactivity Timer: Here, you enter (in minutes) how long you want the mobile device to be inactive for. If you choose '5 minutes' then your mobile will be inactive for 5 minutes, i.e., the app will stop sending you bedtime notifications.

Smart Notifications: If this feature is enabled, then the app will continue to send notifications until your device becomes inactive.

Custom Notifications: Instead of receiving some gentle notification messages, you can edit your settings so that the notifications are more
