

GitLab open sources monitoring and observability tools

A report by *Devops* states that GitLab has made its monitoring and observability tools open source. These tools were previously available as part of the commercial tools in GitLab's DevOps platform.

Kenny Johnston, director of product/ops products for GitLab, said that developers are now using more influence over which monitoring tools are

to be employed. He added that as developers begin to employ monitoring tools early in the application development process, most of them are choosing open source tools. This is because it is unclear whether the application being developed will ever make it into a production environment.

The report said that if the application does make it into a production environment, it becomes difficult for the developers to make a case to fit it on the monitoring tools they were using instead of on an existing commercial offering being used. As per the report, along with reducing costs, the GitLab approach can remove any such potential friction in the DevOps environment.

GitLab also expects that its monitoring tools will benefit from the contributions of a larger community of developers.

AutoGluon has been designed to be an easy-to-use and easy-to-extend AutoML toolkit. It can be used by both machine learning beginners and experts. As per the report, it can enable prototyping of deep learning models with a few lines, automatic hyperparameter tuning, model selection and data processing. It can also provide automatic utilisation of SOTA deep learning models.

AutoGluon aims to eliminate cumbersome processes and deliver developers a better experience. After importing the AutoGluon package, developers can specify a task of interest and load the appropriate data set. AutoGluon can then automatically train various models under different hyperparameter configurations and return the best model.

Facebook releases open source speech recognition platform wav2letter@anywhere

According to a report by *Mobileidworld*, Facebook has announced that it will make its wav2letter@anywhere online speech recognition framework easily available as an open source platform. Developed by Facebook AI Research (FAIR), this platform is being claimed as the fastest open source automatic speech recognition (ASR) platform in the market.

Eight FAIR researchers in a recent paper reported that the system has almost three times the throughput of a well-tuned hybrid ASR baseline. It also has a lower latency and a better word error rate.

The wav2letter@anywhere framework is based on the wav2letter and wav2letter++ neural net language models. It uses time-depth separable (TDS) convolutional neural network (CNN) technology instead of the recurrent neural network (RNN) technology.

Speech recognition has become very common in the recent past. The report said that the joint speech and voice recognition market is expected to be worth US\$ 31.82 billion in 2025.

OCF introduces Universal Cloud Interface to unify the IoT ecosystem through cloud-to-cloud connectivity

The Open Connectivity Foundation (OCF), a leading Internet of Things (IoT) standards body, has introduced the OCF Universal Cloud Interface (UCI). This is supposedly the industry's first solution to unify the IoT ecosystem through cloud-to-cloud connectivity based on OCF's work with open standards.
