

IBM launches Cloud Pak for Security

IBM has launched Cloud Pak for Security that will allow users to connect with any security tool, cloud or on-premise system, without moving data from its original source. The platform will include open source technology to hunt for threats, automation capabilities to help speed up responses to cyber attacks, and the ability to run in any environment, IBM sources claim.

The company said that this open source technology can search and translate security data from a variety of sources, bringing together critical security insights from across a company's multi-cloud IT environment. It is extensible and additional tools and applications can be added over time.

Mary O'Brien, general manager, IBM Security, said, "As businesses move mission-critical workloads to hybrid multi-cloud environments, security data is spread across different tools, clouds and IT infrastructure. This can create gaps that allow threats to be missed, leading security teams to build and maintain costly, complex integrations and manual response plans. With Cloud Pak for Security, we're helping to lay the foundation for a more connected security ecosystem designed for the hybrid, multi-cloud world."

Three initial capabilities of Cloud Pak for Security include being able to run anywhere and connect security openly, gain security insights without moving data, and respond faster to security incidents with automation.

Jolie Tingen, product manager at the Duke University, explained in an article at *Educause Review* that no monolithic system can provide all learning communities with a completely optimal experience. Tingen added that learning is maximised when appropriate technologies are used in conjunction with evidence-based pedagogies.

Kits features a card for every course, and instructors can add apps to their kits. These apps get automatically shared with everyone in their courses. The alpha version of Kits has been released.

Presently, eight applications are included in Kits and three more are likely to be added this year. The report said that learning analytics is also on the road map.

Debian 10.2 released

This Debian point release mainly adds corrections for security issues, along with a few adjustments for serious problems. Security advisories have already been

published separately and are referenced where available in Debian's distribution repositories.

Users must note that the point release does not constitute a new version of Debian 10 but only updates some of the packages included. There is no need to throw away old Buster media. After installation, packages can be upgraded to

the current versions using an up-to-date Debian HTTP mirror.

Those who frequently install updates from security.debian.org won't have to update many packages, and most such updates are included in the point release.

Google envisions switching to the mainline Linux kernel for Android

Google revolutionised the smartphone space with its Android OS built on top of a custom Linux kernel not very different from the millions of other devices around the world at the time.

This initial fork of the mainline Linux kernel at its peak ballooned up to a whopping 60,000 lines of extra code, which has now been reduced to 32,000 and this number is still falling – thanks to recent cleaner code maintenance and debugging processes advocated by Google and The Linux Foundation to

maintainers and contributors working on Android and other open source toolkits.

The Google team realised over the years that although the initial benefits of forking the mainline kernel resulted in faster development and prioritised smartphone and other mobile-centric feature sets, it also created a lot of additional code maintenance. This

was apart from the upstream development of the standard Linux kernel and hence, effectively forced Google's resources to be bogged down in re-inventing the wheel.

This was however manageable over the years with exponential improvements in the system resources of the devices Android runs on and the infrastructure it is developed and built upon.

Google has finally addressed the elephant in the room and highlighted the state of kernel updates on popular Android devices. Currently, most OEMs shy away from integrating kernel updates from upstream and make do with only publishing security
