

card, that is also a possibility. Or if a country wants to print a smart card, then MOSIP provides an interface for smart card printing.

So now, countries are getting interested in MOSIP.

System design for easy integration

ABIS (automated biometric identification system) is required for duplication. For example, an ID card like Aadhaar should be easily verifiable, whichever part of the country one goes to. Our system can integrate with multiple ABISs available in the world. A country is free to choose its preferred ABIS and integrate it with another device of its choice. MOSIP is completely configurable in terms of language, credentials, etc.

However, certain components of the ID platform haven't been built yet, but we might do so in the future. As the platform is open source, developer contribution is required. Some of the things we haven't built are listed below.

- **Hardware:** This includes the fingerprint scanner, iris scanner or

a camera.

- Analytics
- Fraud detection

MOSIP principles

As shown in Figure 1, and as stated earlier, certain components, like analytics and fraud detection, have not been included in this version. These components are available on various open source platforms and anyone can contribute towards them.

The modules currently available in GitHub for MOSIP are:

Featured below are a couple of questions from the audience that were answered at the end of the talk.

Q. There is a shortcoming in Aadhaar related to fingerprint and iris detection for those people who are over 80 years old. So how do you plan to tackle that?

A. You can choose to do away with biometric identification and instead use a QR code.

Q. As per your GitHub repository, the platform is based on a centralised architecture. Why did you not opt for a decentralised architecture like blockchain?

A. There is a blockchain council that is working with us on future projects.

- Pre-registration, in which you book your slot to register yourself and provide basic information
- Registration (for offline or online)
- Fingerprint, photos and ID
- Registration processor (generation of a random number, which does duplication of ABIS)
- Identity authentication. For example, you can generate a QR code and use that instead of a UIN (unique identification number). The QR code will have all the data for authentication.
