

How Blockchain is Aiding the Software Development Industry

This article highlights the use of blockchain technology in software development and how it's reshaping the entire software industry.

Blockchain technology is growing in leaps and bounds, and this technology is now also being used in software development. It addresses the various challenges faced by the software industry to ensure productive testing activities, enhanced collaboration within teams and the use of smart contracts in software development.

What is blockchain technology?

Blockchain is an emerging technology that is disrupting the current

technology paradigm. It can unleash the potential of data used to develop next-generation software. Blockchain is a time-stamped sequence of immutable records of data managed by a cluster of computers and not by a single entity.

Blockchain technology is a decentralised and unbreakable electronic ledger. It is used to record economic transactions. It is a highly reliable technology for transparent data transfer. It follows the principle of blocks in a chain, where each of these blocks is secured.

Why use blockchain for software development?

When an application is developed using blockchain technology, the user has the authority to view and add a record to the software database. The user can't modify or delete any data record, which improves the integrity of the entire process. Another benefit of blockchain is that it stores data in transparent ledgers and data traverses through peer-to-peer networks.

The increase of mobile applications with enhanced security and higher quality has led to the rise
