

Six Things to Consider for a DevOps Transformation to the Cloud

The COVID-19 reality has pushed the market towards faster adoption of remote access to IT by developers. Software vendors are therefore in a race to enable and expand cloud DevOps solutions. Increasingly, teams seek to adopt end-to-end DevOps platforms or tool bundles that decrease their reliance on multiple vendors and give them ownership of the tooling infrastructure. But what should an enterprise demand from cloud DevOps tooling, and what key differentiators should be considered?

Here are six things one should consider when engaging with any individual vendor for a DevOps digital transformation to the cloud.

End-to-end (E2E) solutions

Developers today are looking for an E2E solution and an all-in-one user experience. However this doesn't mean that they will compromise on the 'best of breed' approach. Therefore, DevOps

platform providers should offer a Class A tool stack as part of their platform, in addition to very strong ecosystem integrations and plugins to make developers' lives easier, respecting the freedom of choice they want.

An E2E platform also requires a vendor commitment to allow a true 'one-browser solution' and not simply bundled tools that are integrated. This ensures that the user will have a full experience from a single UI that connects all services.

Universal package management

All of the metadata and dependencies in your myriad technologies must be supported (such as Docker, npm, Maven, PyPi, Golang, NuGet, Conan, etc – but also the 20+ more that you may find in your portfolios). Point solutions for single or limited technology types will only serve to frustrate your development teams and require the adoption of multiple solutions and repositories within your organisation. Large enterprises have
