Figure 1: Comparing cloud based end-to-end DevOps solutions

not only myriad technologies, but also a long legacy of deployed, mission-critical applications that must be supported at scale with local, remote and virtual repositories.

Both cloud and on-premise solutions need to be integrated 100 per cent

This isn't about whether or not to have a cloud solution. Many companies that offer cloud solutions don't have corresponding on-premise/self-hosted options, or vice-versa. More still

have completely separate solutions that provide different features and methods that don't talk to each other, requiring you to learn a new product, user experience and user interface. As you transition to a cloud environment, both cloud and on-premise solutions need to be able to function in the same way 100 per cent of the time to ensure a smooth transition. For instance, as you go through a cloud migration, you will need the same tools and functions in both places in order to keep the business running.

Multi-cloud

While you might think one cloud is enough, you should select a vendor that provides services across and between all major clouds. Keep your options open and your peace of mind intact by avoiding any vendor lock-in and providing maximum resilience.

Security

Security is an integrated part of the pipeline that supports all of your package types and it is now a line-item for many companies.
