

Cloud DevSecOps tools should make it possible to block artifact downloads (or break builds) that contain vulnerabilities, requiring tight integration all the way into the repository. Security policies should be easy to define and manage across your repositories. And any cloud security solution should allow you to easily identify the impact of a vulnerability across the entire DevOps pipeline.

The world of containers also comes with a challenge. Your DevSecOps tools should be able to ‘open’ any container and scan several tiers in, and with all packages look for dependencies that include vulnerabilities.

A DevOps platform should always strive to be ahead of any hacker and

secure all software packages in the pipeline from build-to-production.

Cloud-ready CI/CD

Traditionally, application development teams were responsible for creating localised CI/CD (continuous integration/continuous delivery) automation. This approach provides short-term gains for the individual teams but ends up being a constraint in the long run since enterprises get no economies of scale across their CI/CD implementations.

A modern CI/CD provider should support and scale enterprise-wide workflows (aka the ‘software supply chain’) that span all popular technologies and architectures

of today as well as keep pace with technology evolution. It should provide a way to assemble pipelines from pre-packaged building blocks, rather than developing them from scratch. These pipelines can be templatised and shared as libraries across the organisation, thereby building a knowledge base that is constantly growing and improving. In other words, your CI/CD provider should give you economies of scale over time in the cloud, and help you ship code faster. **END**

Another such attempt comes from IIT Delhi, where a research centre has been built to assist the capital’s police for such purposes as criminals’ identification, cyber policing, traffic management, and combating crimes by using artificial intelligence (AI), biometrics, image processing, Big Data, social media analysis and network forensics.

Technologies like AI, analytics, blockchain, and cloud computing are making their way into the courtrooms, too. AI-powered tools can be used by lawyers for most daily tasks, from reviewing documents and performing legal research rapidly to predicting various outcomes of a case. Businesses can utilise AI to review contracts for partnerships without any bias, and perform background checks before hiring new employees to avoid getting into legal troubles later.

Several companies in countries like the US, Singapore, the UK, Canada and Australia are using technologies to solve issues in this space.

Canada-based Kira Systems uses machine learning (ML) for contract

analysis. UK’s Tessian employs AI to secure confidential data and emails for law firms.

In India, researchers from IIT Kharagpur have recently developed an AI-powered method to automate the reading of legal case judgements, case law analysis and enhance legal search across several domains. Deep neural models enable understanding the rhetorical roles of sentences or jargons in a judgement when adequate data is available, and hence aid in organising legal documents.

Blockchain finds application in email encryption, verifying processes and securing evidence, like in financial transactions and many other purposes. For example, Legaler’s blockchain and developer tools provide infrastructure to build decentralised applications for legal services. In 2017, Global Legal Blockchain Consortium was formed to drive the standardisation of blockchain technology in the legal sector. It has already surpassed 150-member mark,

which includes law firms, software companies, and universities, among others.

According to a 2019 report titled LawTech Adoption Research by tech analysts TechMarketView, the number of lawtech companies has grown over the past few years, but the adoption rate is not that high among legal practitioners. One of the major reasons noted behind this is the partnership model in which spending is done from the partners’ profit pool.

To change this scenario, the US states like North Carolina and Florida have already mandated technology training for CLE (continuing legal education) credits. Pressure from clients for cheaper offerings is also pushing law firms to move to cloud computing and other tech solutions. **END**
