

How DevOps Differs from Traditional IT and Why

DevOps is the buzzword in the software development industry. But how much of the hype associated with this new technology is warranted? This article demystifies DevOps and explains to the reader why it scores over traditional IT practices.

DevOps is a set of practices that promotes partnership between the development and operations teams to deploy code to production faster in an atomically and continuous manner. The word 'DevOps' is a combination of the words 'development' and 'operations'.

DevOps helps to increase an organisation's speed to provide applications and services. It allows companies to serve their customers better and compete more powerfully in the market. In simple words, DevOps can be interpreted as an arrangement of development and IT operations with better communication and collaboration.

Why it is needed

- Before DevOps, the development and operations teams worked in a completely segregated way.
- Testing and deployment were different activities done separately after design-build. Hence, they required more time.
- Using traditional IT practices, team members spent large amounts of their time in testing, deploying and designing, instead of building the project.
- Manually deploying the code leads to human errors in production.
- Different teams have different timelines. This leads to problems

of synchronising timelines, causing more delays in deployment.

Comparing DevOps and traditional IT

When comparing traditional IT ops with DevOps, it's clear how they differ and why the latter is increasingly embraced by organisations worldwide. Given below are some points of comparison.

1. Time

DevOps teams spend 33 per cent more time to refine infrastructure against failure than traditional IT ops teams. In addition, DevOps teams spend about 21 per cent less time putting out fires on a
