

Figure 3: DevOps addresses the communication gaps between the developer and IT operations teams

Differences between agile and DevOps

Parameter	Agile	DevOps
What is it?	Agile refers to an iterative approach that focuses on collaboration, customer feedback and small, rapid releases.	DevOps is considered a practice of bringing the development and operations teams together.
Purpose	Agile helps to manage complex projects.	DevOps' central concept is to manage end-to-end engineering processes.
Task	The agile process focuses on constant changes.	DevOps focuses on constant testing and delivery.
Implementation	The agile method can be implemented within a range of tactical frameworks like 'sprint', 'safe' and 'scrum'.	The primary goal of DevOps is to focus on collaboration, so it doesn't have any commonly accepted framework.
Team skillset	Agile development emphasises training all team members to have a wide variety of similar and equal skills.	DevOps divides and spreads the skillset between the development and operations teams.
Team size	A small team is at the core of agile. Because the smaller the team, the faster they can move.	Relatively larger team size, as it involves all the stakeholders.
Duration	Agile development is managed in units of 'sprints'. This time is much less than a month for each sprint.	DevOps strives for deadlines and benchmarks with major releases. The ideal goal is to deliver code to production daily, or every few hours.
Feedback	Feedback is given by the customer.	Feedback comes from the internal team.
Target areas	Software development	An end-to-end business solution and fast delivery.
Shift-left principles	Leverages shift-left	Leverages both shift-left and shift-right.
Emphasis	Agile emphasises on the software development methodology to create software. When the software has been developed and released, the agile team will not care what happens to it.	DevOps is all about taking software that is ready for release and deploying it in a reliable and secure manner.
