

myApp folder structure:

The `index.html` is the starting page of the application. Depending on the deployment technology stack the file/extension can be `index`, `index.php`, or `index.cgi`, or `index.pl`, or `index.shtml`, or `default.html`.

The default starting page must be configured in the respective web server.

Figure 1: SPA folder structure

including databases. However, the full-stack developer doesn't know all the developments related to every platform or framework, and that's the current problem being faced.

Problem 3: Earlier, developers used to do programming in BASIC or FORTRAN. For them, the Web was just CGI or Perl. They used to dump all the code in a particular Perl file including HTML, Perl scripts, etc, but it used to be a nightmare to manage this. Then developers started using Java, but even Java servlets were painful. They wrote HTML code under double quotes, which was a horrendous task for HTML developers. So, they needed a separation, like the MVC framework. But after the launch of JSP, which is similar to HTML with the integration of simple JS, developers are now using JSP with a lot of JavaScript and less HTML, leading to complexity of the code. The problem is that developers seem to be mixing JS, HTML and even CSS, making things even more complex.

The first law of software quality is $e=mc^2$ (errors=(more code)²). This implies that the more the code, the more the errors. Just take an example of Angular or React. The seed project that we download with

one `package.json`, with one or two files like `index.html`, does not allow us to start our project. We now need to do a `npm install`, which downloads approximately 120MB of code. And all this needs to be done even if you need to just demonstrate 'Hello World'.

We think that we are writing less code but, unfortunately, we are not — it is more likely we are writing less code as someone else has already written it, and we have installed it along with our seed project.

Steve Jobs explained the problem like this, "The way you get programmer productivity is not by increasing the lines of code per programming per day. That doesn't work. The way you get programmer productivity is by eliminating the lines of code that you have to write. The goal here is to eliminate 80 per cent of the code that you have to write for your app. That's the goal. I've seen a lot of demos that try to take it all the way back into the algorithmic part of the code base, and none of them have ever been any good." So, the less the code, the fewer the errors, and the higher the productivity.

Let us get back to SPA JS

To get started, visit <https://spa.js.org/>. The site has all that is needed to

learn and use SPA JS. Also, it is on a pure MVC framework that provides flexibility to developers.

The structure is well organised, which helps to reduce the code complexity. Even when the developers try to mix up the code, SPA JS will not allow it. It has a clear view that is separated with three layers — one layer with pure HTML content, the second with all the controls, and the data layer (which is entirely API driven) that helps to build the perfect bridge. One of the significant problems with Angular.js is that the features keep on updating periodically, and it is challenging to teach developers these features and frameworks. SPA JS has tried to address this issue. The site also has all the guides, so developers don't need to Google for a solution. **END** 🐧
