

GitHub sets up office in India

GitHub has opened a subsidiary in India called GitHub India Private Limited. The company said it aims to serve the developer community and GitHub's enterprise customers in India in a better manner. It also said that GitHub's community of developers in India has been growing at a rate of 22 per cent over the past year. India has the third-largest number of active developers on GitHub after US and China. Erica Brescia, chief operating officer, GitHub, said, "As the third-largest group of active developers on GitHub, Indian developers are truly building the future of software. Over the past year, the number of public repositories in India has grown 75 per cent, demonstrating a sharp

increase in collaboration across the Indian developer community. In building a local team in India, our goal is to create stronger relationships with developers and support open source development across developers, maintainers and enterprises."

GitHub's India operations will be led by Maneesh Sharma as general manager. The company will build a team across functions like community, engineering, sales, support, marketing and services in the next few months. It aims to enable customers to adopt DevOps best practices at scale, and collaborate with over 40 million developers on more than 100 million projects.

Bi-directional Encoder Representations from Transformers (BERT) is a self-supervised method that was released by Google in 2018. The method delivered results on a range of NLP tasks by depending on un-annotated text drawn from the Web.

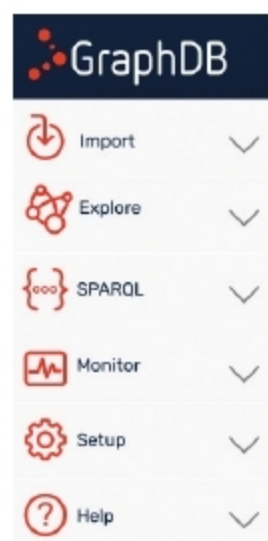

According to a report by i-programmer, ALBERT is an upgrade to BERT. It offers improved performance on 12 NLP tasks, which include Stanford Question Answering Dataset (SQuAD v2.0) and the SAT-style reading comprehension RACE benchmark. ALBERT has been released as an open source implementation on top of TensorFlow. It will include various ready-to-use pre-trained language representation models.

Quoting a paper submitted by its developers to the International Conference on Learning Representations, the report said ALBERT reduces model sizes in two ways—by sharing parameters across the hidden layers of the network and by factorising the embedding layer.

Ontotext makes new version of GraphDB open source

According to a report by i-programmer, Ontotext has made a new version of GraphDB open source. This version comes with a range of new plugins. The report added that GraphDB Workbench, which gives developers a way to develop knowledge graph prototypes, was also made open source as a separate project.

GraphDB 9.0 aims to make it easier for developers to create and operate knowledge graphs. It does this by opening multiple integration extension points. GraphDB is a Resource Description Framework (RDF) or triple-store database. It uses the RDF4J framework interfaces and the W3C SPARQL Protocol specification.

The report said that the new design has a redesigned database plugin API, which makes it simple to implement complex software logic to the core database engine. The company has made many plugins open source, and demonstrated ways to solve tasks like data virtualisation with the MongoDB plugin. A GraphDB GeoSPARQL
