

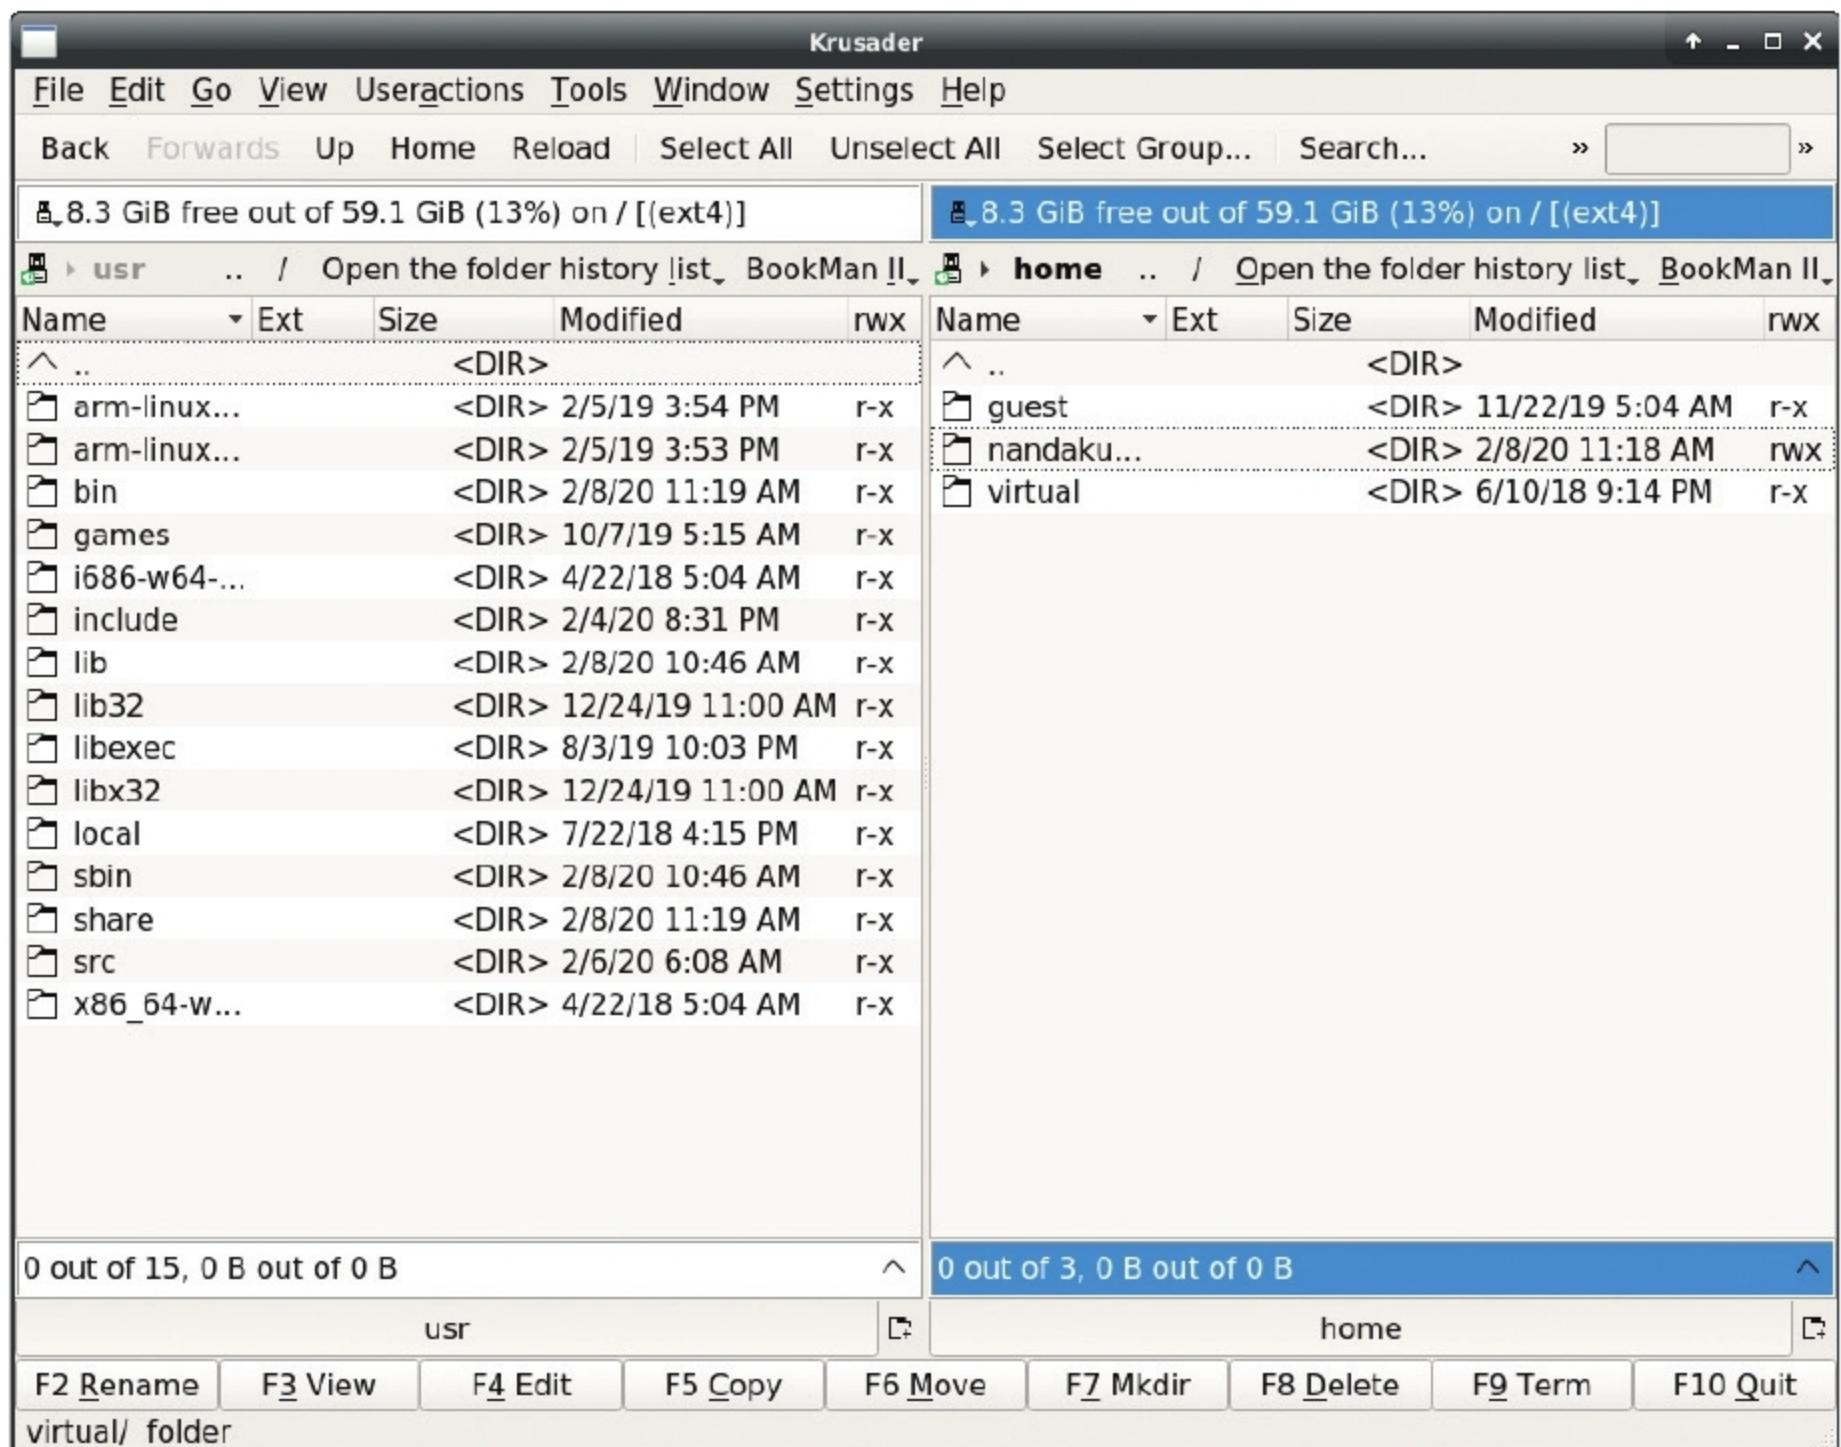

Figure 1: Krusader orthodox file manager

There are other kinds of file managers, like orthodox file managers, 3D visualisers, etc. Orthodox managers usually provide two listing panes and a console pane. GNU Midnight Commander (*sudo apt install mc* in Debian based systems) is a text-based orthodox file manager, which means it works in the console (suitable for server management). A popular GUI counterpart is Krusader. It is advanced and capable of taking advantage of several low-level tools.

The power of commands: Those who have a grip on the command line interface will find it easier to manage files using the classic commands *ls*, *cp*, *mv*, *mkdir*, *rm*, etc, in certain

scenarios. However, there is always the next level.

What if you want to find all files with the extension *.txt*? You can use the command *ls *.txt*, of course. But what if you want to perform a case-insensitive search for all files in all sub-directories that has the word 'receipt' somewhere in the path and has a name that ends with *.pdf* or *.txt*? The trick is to combine multiple commands:

```
find . -type f | grep -iE '.*receipt.*\.(pdf|txt)'
```

The full explanation of the above command is beyond the scope of this article. The 'find' command is used to

list all the items in a given directory (and its children, recursively), while we can use the *grep* command to filter its output using regular expressions.

grep can also search inside files, and there is *sed*, which can perform editing also. If you are a programmer and want to rename a certain variable in multiple source files, *sed* is the tool you are looking for.

Bulk renaming: Selecting multiple files and choosing the *Rename* option will pop open the bulk renaming dialogue in some file managers like Nautilus and Thunar. There are standalone tools, too, which include *krename*.
