

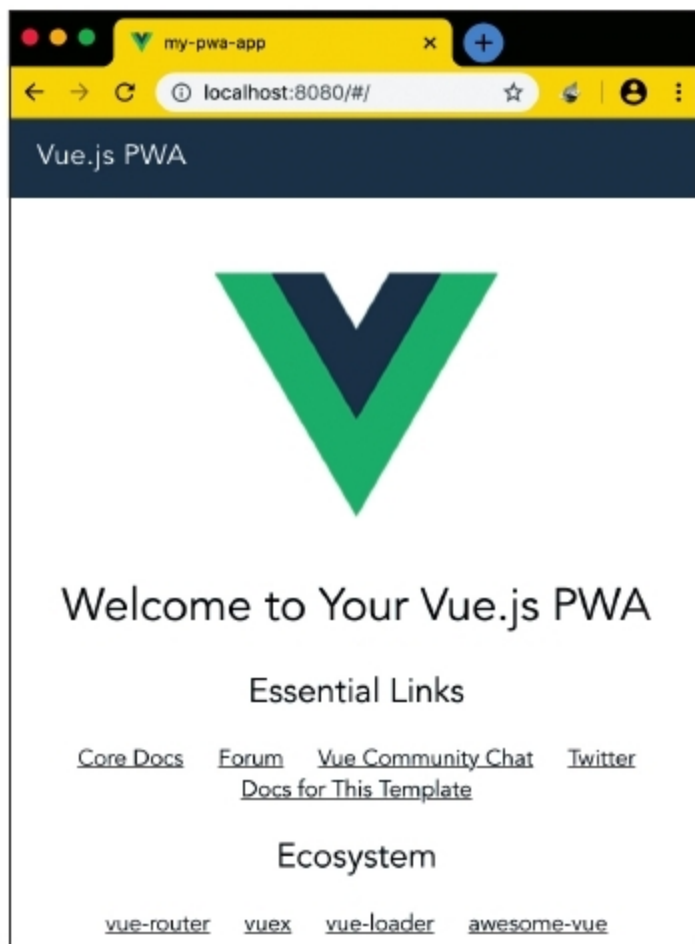

Figure 2: Your PWA running on a development server

Creating a PWA with Vue.js

Before creating the app, I would recommend installing Visual Studio Code (VSCode) for this project. VSCode is an open source code editor developed by Microsoft and is popular among developers. It is absolutely okay to use any other code editor as well, but the integrated terminal facility in VSCode makes it ideal for this project. Now, take the following steps.

In the terminal, navigate to whichever directory you prefer to save the project in, and run the following code:

```
vue init pwa my-pwa-app
```

The PWA template will get initialised and you will be asked to provide a few details such as the name of the app, the author, description, etc. You can provide the details or simply skip this by pressing the return key. Figure 1 shows the procedure for initialising the PWA.

Making sure that you are in your project directory, run the following line

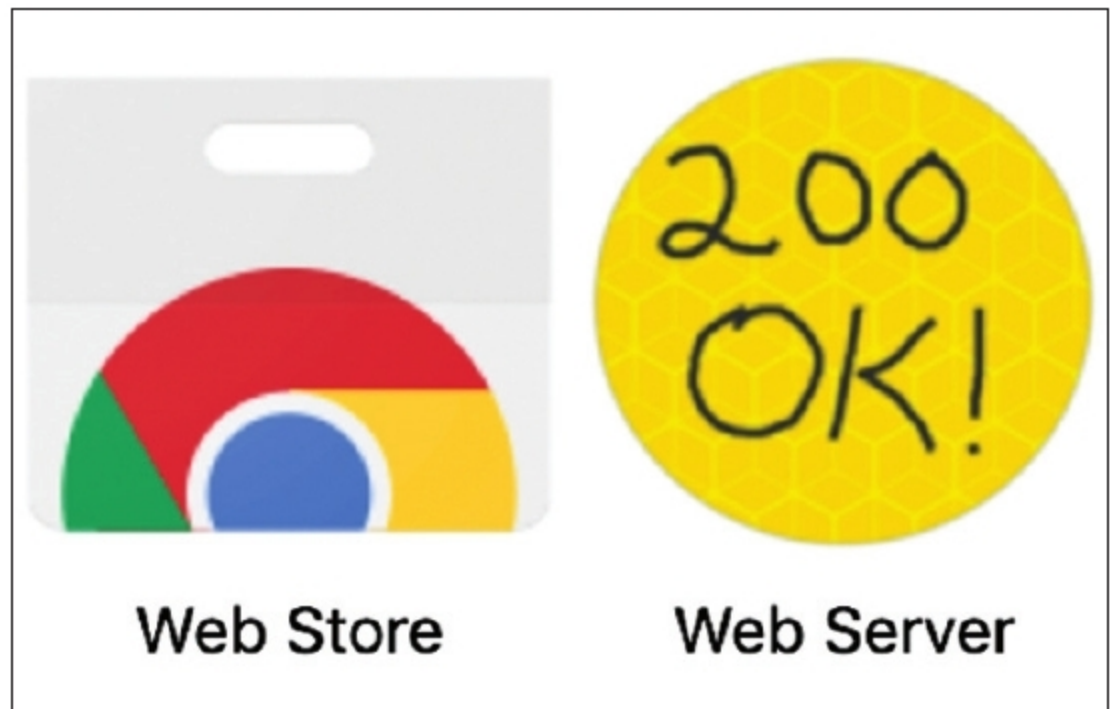

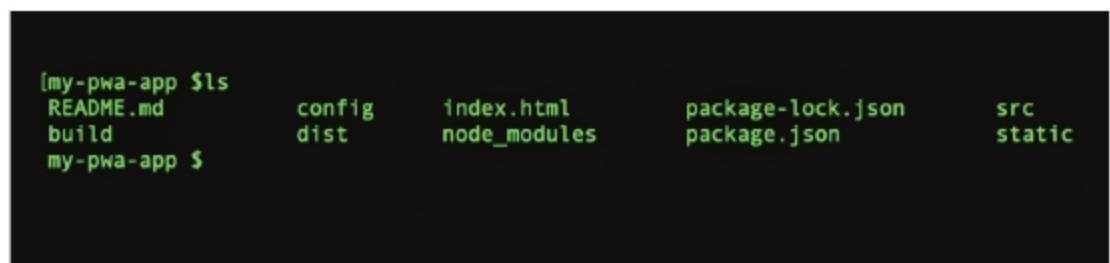

Figure 3: 200 OK Web server app

Figure 4: A new *dist* folder in the project directoryFigure 5: Add the path to the *dist* folder in the 200 OK Web server app

of code to install *npm* into this project:

```
npm install
```

And that's it! Your app is now ready. You can run it using the following code:

```
npm run dev
```

Your app is now running on a localhost development server as shown in Figure 2. However, you will not be

able to use the app as a PWA because running the latter requires you to run it on an HTTP server. In order to tackle this problem, we will download a simple HTTP server app on Chrome that will host our app for us.

Now open the Chrome browser and Google '200 OK chrome'. The first search result you see will be of the Chrome Web store. Go ahead and install the app. After doing so, you should be able to see it at *chrome://apps*, as shown in Figure 3.
