Figure 3: AChecker home page

![Screenshot of the AChecker 'Accessibility Review' results page. It shows a summary with 'Known Problems (223)', 'Likely Problems (0)', and 'Potential Problems (2228)'. The '1.1 Text Alternatives: Provide text alternatives for any non-text content' section is expanded, showing a 'Check 1: img element missing alt attribute' error. The error details include the line number 'Line 452, Column 11' and the HTML code snippet: '<img height=\\\](\\\"https://www.facebook.com/tr?id=20324570335372)

analysis — A, AA and AAA, with an increasing set of rules to be satisfied at each level. A page with no errors in Level A may show some errors if checked against the standards mandated for levels AA or AAA. It is better to test your pages with the

AA level to make sure that it shows no errors at that level, at the very least.

The POUR principle

The WCAG incorporates four major accessibility principles, which are together known as POUR – perceivable, operable, understandable and robust.

- **Perceivable:** The information that is put on the Web page should be easily identifiable for the user. Access to it should not be restricted to people using only one of their senses, such as only visual perception. Access to the page should be provided through more than one sense.
- **Operable:** The controls that are provided in the user interface should be such that users can easily use them, successfully.
- **Understandable:** Content that can be perceived by users but not understood by them is still inaccessible. For example, the target audience should be able to comprehend the language used unambiguously.
- **Robust:** The accessibility features provided should not be reliant on one particular type of technology or set of tools. They should be robust enough to accommodate users employing multiple types of technologies.

Tools for accessibility analysis

Unfortunately, many websites do not incorporate accessibility due to the reasons mentioned earlier. The first step in building an accessible Web ecosystem is to measure the state of accessibility of an existing website. There are many tools available to perform accessibility analysis. Some of them are listed below:

- AChecker
- WAVE
- AATT (Automated Accessibility Testing Tool)
- Accessibility Viewer
- aXe chrome plugin

There is a longer list of tools provided by the W3C on the Web Accessibility Initiative (WAI) page. You may navigate to the following link to explore these further: <https://www.w3.org/WAI/ER/tools/?q=wcag-20-w3c-web-content-accessibility-guidelines-20>.
