

Every language has its own libraries. To be a good programmer, it is not necessary to know all the libraries there are in any language. However, there are some libraries that every developer should know well.

The integrity of Python has led to many developers building fresh libraries for it. Because of the vast number of libraries, Python is becoming very popular among machine learning professionals too.

So if programmers get to know the following 23 libraries really well, they can accomplish a lot in their day-to-day jobs.

TensorFlow

If you are working on a machine learning (ML) project in Python, then you might have heard about this famous open source library known as TensorFlow. It was originally developed by Google in partnership with Brain Team. TensorFlow is used in every Google application for machine learning.

Matplotlib

A must for data testing and analysing, Matplotlib is an analytical plotting library commonly applied in the Python scientific computing community. It gives an object-oriented API for embedding plots into applications, using general-purpose GUI tool kits like Tkinter, wxPython, Qt or GTK+.

NumPy

This library provides advanced math functionalities and an integral package for scientific computing with Python. NumPy is regarded as one of the most popular machine learning libraries in Python.

Requests

This is a must-have for Python developers. It authorises you to send HTTP/1.1 requests, and to add headers, form data, multi-part files and restrictions with simple Python

dictionaries; and to access the feedback data in the same manner.

SQLAlchemy

This offers a full suite of well-known enterprise-level endurance patterns, created for adequate and high-performing database connections, and modified into a simple and Pythonic domain language.

Pandas

Pandas provides fast, flexible and suggestive data structures, created to carry out working with structured (horizontal, multi-dimensional and probably heterogeneous) and time-series statistics, both simple and intuitive.

Pillow

A friendly fork of PIL (Python Imaging Library), Pillow is a free library for Python programming, which also adds support for opening, manipulating and saving different image file formats. It is available for Windows, MacOS X and Linux. Being user-friendly, it is a must-have for everyone who works with images.

Beautiful Soup

This is a Python package for viewing HTML and XML documents. It makes a parse tree for parsed pages that can be used to extract data from HTML, which is effective for Web scraping. It may have limited functionality but its XML and HTML parsing library is extremely helpful for beginners.

SciPy

This is one of the foundation packages that drive up the SciPy stack. It presents many user-friendly numerical routines, such as programs for numerical integration and development. The essential component of the SciPy library is that it is produced using NumPy. Its array makes the most use of NumPy.

Pygame

This offers an incredibly easy-to-use and robust Python interface to the Simple Directmedia Library (SDL)

platform-independent graphic, audio and input libraries.

Scrapy

This provides a fast, high-level screen scraping and Web crawling framework. It can be used for many purposes – from data mining and monitoring to automated testing.

Twisted

This is actually an event-driven networking engine written in Python and certified under the open source MIT licence. Twisted runs on Python 2 and a forever-growing subset also runs with Python 3.

Pyglet

This library provides an object-oriented programming interface that is helpful when developing games and various other visually-rich applications specifically for Windows, MacOS X and Linux.

wxPython

This is a wrapper around wxWidgets for the Python programming language. It is the cross-platform GUI API wxWidgets for the Python programming language, and is one of the substitutes for Tkinter, which is packed with Python. It is carried out as a Python extension module.

pywin32

This is a Python library that provides some useful methods and classes for interacting with Windows.

iPython

This is based on an architecture that produces parallel and distributed computing. iPython enables parallel applications to be built, executed, debugged and monitored interactively.

Nose

This library gives an alternate test result and running process for system tests, one that is designed to simulate the action of *py.test* as often as is logically possible.
