

A Quick Look at Web Optimisation Tools and Techniques

Ever since the invention of search engines and page ranking algorithms, organisations have been competing for the top spot on Web search results. Here are a few tips to help you do that.

Google is the place everyone goes to, when it comes to searching for information. Be it reports, shopping, learning, finding places to visit and a whole lot else, Google knows it all.

So, how does this happen? Google keeps on collecting, analysing and indexing data all the time. It collects data from different websites and then gives us the most trustworthy results, which are based on over 200 factors. And let's face it, the Internet is a huge space, with a lot of articles, blog websites and even user searches, and the amount of data that Google stores is massive. Organising and fetching this kind of data is a monstrous feat. This is where Google's page ranking comes in.

Page ranking involves the evaluation of a website on a number of factors. The important factors to take care of for a higher rank are:

- A secure website
- An accessible website
- Domain age and URL
- Content quality
- Quality backlinks
- Social signals
- User experience
- Business information
- Technical SEO
- Page speed

A secure, crawlable website

The first factor is obviously related to the type of website you have. With so much of personal information floating about online, security is one of the key factors considered by the developer. Even the end user today knows that a website with HTTPS is more secure and trustworthy. Though not such a critical factor, having HTTPS is great for the user and the website.

How is HTTPS different from HTTP?

HTTPS is just the secure version of HTTP and works by hand shaking with another protocol, which is the secure sockets layer (SSL). This provides dual benefits — HTTP ensures that all data gets to the user and SSL secures the data exchange.

Another important aspect is whether the Google bots are able to easily reach and crawl your website. The bots must be able to reach the URL, read and understand the contents, and determine what your website is about.

Some ways to achieve this is by having:

1. A well coded website
2. Include a robots.txt file that tells Google bots where to find your site information
3. A site map
