Argus

Argus (audit record generation and usage system) is a real-time flow monitor that is designed to perform comprehensive data network traffic auditing. Argus is supplied as source code, so to really get started, you need to compile and install the software onto a ported system. Argus has been ported to all flavours of Linux and most UNIX and other OS that are available, including Solaris and Cygwin-enabled Windows systems.

Argus processes packet data and generates summary network flow data in real-time. If you have packets and want to know what's going on, Argus is a great way of looking at aspects of the data that you can't readily get from packet analysers. It answers questions like how many hosts are talking, who is talking to whom, how often, is one address sending all the traffic, are they doing bad things...etc. Argus is designed to generate network flow status information that can answer these and many more questions that you might have.

Many sites use Argus to generate audits from their live networks. Argus can run in an end-system, auditing all the network traffic that the host generates and receives. It can run as a standalone probe, running in promiscuous mode, auditing a packet stream that is being captured and transmitted to one of the systems network interfaces. This is how most universities and enterprises use Argus, monitoring a port mirrored stream of packets to audit all the traffic between the enterprise and the Internet.

The data is collected to another machine using *radius()* and is then stored in what we describe as an Argus archive, or a MySQL database. From there, the data is available for forensic analysis, or anything else
