

you many want to do with it, such as performance analysis or operational network management.

Vault

Vault by HashiCorp helps you secure, store and tightly control access to tokens, passwords, certificates and encryption keys to protect secrets and other sensitive data using a UI, CLI, or HTTP API. Vault supports most of the platforms available in the market, making it a key security tool.

It has three major areas of focus, as listed below.

Secret management:

- Dynamically create, revoke and rotate secrets programmatically.
- Encrypt data while at rest, in the storage backend.
- There are multiple pluggable identity backends.
- There is a detailed audit log of all client interaction.

Figure 4: Vault

- Users can manage authorisation and create time based tokens.

Data encryption

- There is a centralised workflow to encrypt data in flight and at rest.
- AES 256-bit CBC data encryption and TLS in transit.
- Users can update and roll new keys throughout distributed infrastructure.

Identity based access

- There are policy and access control decisions across platforms.
- Requires multiple identity entities to authorise a requested action.
- Centralised location to manage policies to authorise access across organisations.
- MFA workflows when accessing a secret or a secret path.
