

page if there are any, which is useful for debugging. However, something like that in production will let users see your PHP errors, which can be a major usability and security concern.

To set up the configuration, rename the `php.ini-development` file to `php.ini` in your PHP installation directory. PHP is now configured to be used in a development environment.

Test running a dynamic page

To test if PHP is working correctly, just head over to your document root, delete the original `index.html` file and create a new file called `index.php` with the following content:

```
<?php
phpinfo();
?>
```

Now restart your Apache service at *Windows Services* and reload `http://localhost` on your browser. You should see something like what's shown in Figure 3.

This page shows you all the configuration settings in PHP.

If you have made it this far, congratulations! You have successfully set up PHP in your Windows computer.

You can now enable certain modules, based on your needs, by modifying the `php.ini` file and simply uncommenting the lines. For example, to enable `mysqli` support on PHP, you need to find and uncomment the line:

```
;extension=mysqli
```

Then change it to:

```
extension=mysqli
```

After this, simply restart the server to start using the `mysqli` module, which allows you to connect to a MySQL server. Now you can edit the PHP file to

build dynamic websites. If you are new to PHP development, a good starting point is to start with the PHP documentation provided at <https://www.php.net/manual/en/index.php>.

That's all there is to it. PHP has been set up with Apache to be able to serve dynamic Web pages written in PHP. To deploy it in a production environment, simply rename the `php.ini-production` file to `php.ini`.

However, there are a few more things to take care of when deploying in production, especially at the Web server level.

You can find a better tutorial geared towards deploying a LAMP system securely to production at <https://opensourceforu.com/2019/05/securing-a-lamp-server-in-2019/>. **END**

An important feature of Chrome is that it alone supports the Nexus device or its hardware. So, if you are a Google fan, you can definitely enjoy Chrome OS with Chromebook.

8. TempleOS

TempleOS has been set up from the grate up with, it seems, no connect with existing operating systems. The entire work is hyperlinked, in the sense that you can quickly delve down to the source of a program just as rapidly as you can discover its dependencies, and it is super-quick. There're no beeps, so the whole OS gets up and functioning within a second or two.

Remarkably, considering this OS was created entirely by one man, Terry Davis, you'll be able to use TempleOS for everything substantial. Sadly, Davis' well-documented mental health issues haven't helped the OS' standing

Figure 8: TempleOS

in the community. But TempleOS consists of a vast number of exciting ideas, especially the softening of the

division between a document and a program, which could impact more conventional operating systems. **END**
