can be pulled once the EC2 instance is up and registered as a Jenkins node, after which you can initiate the suite execution on the latest code.

Automation tool — Katalon Studio: In the setup, we used Katalon Studio to automate the test suites. Katalon Studio is a free automation testing solution. It is built on top of the open source automation frameworks like Selenium and Appium, with a specialised IDE interface for the API, the Web and mobile testing. The test automation framework provided within Katalon Studio has been developed with a keyword-driven approach as the primary test authoring method, with data-driven functionality for test execution.

Cloud storage service – AWS S3: After executing the automated test, the reports can be easily stored in any cloud storage service, depending on the

buckets, S3 is a good choice to store date-based reports of the execution.

Once the complete suite is executed, the reports/recordings can be maintained under a date-based folder structure in an S3 bucket for any future references. Life cycle policies for the S3 bucket can be used to move objects from S3 buckets to cold/archival object storage, i.e., Amazon Glacier, to further reduce the cost.

Terraform is cloud-agnostic architecture for automated test execution. It is stable, reliable, scalable and has many cost benefits. Since the test environment is built and terminated dynamically at runtime, users only pay for what they use. Also, one is not tied to one cloud service provider because of the flexibility to evaluate and choose. Migration, too, is hassle-free. The ultimate goal is to design a solution that gives the maximum ROI on any test automation project and helps deliver a high quality product with agility. **END** 🐧
