

cloud management and helps users prevent vendor and complexity lock-in. It offers cost and usage reporting, RBAC, management, provisioning, orchestration, monitoring and automation for servers across public and private clouds, Docker containers and KVM hypervisors. It gives actionable alerts so users can address operational issues from anywhere, using any Web-connected device.

Mist.io offers a unified interface for performing common management tasks like provisioning, orchestration, monitoring and automation. It works from any device, including laptops, tablets and phones, to help users take action from where ever they are. Due to the RESTful API and command line tools, it's easy to integrate it in the user's existing workflow. Because Mist.io abstracts the infrastructure level, users can replicate the entire setup across providers in a matter of seconds. It's a freemium service with an open source component that aims to become the de facto standard for multi-cloud management and a broker of cloud computing services. It's targeted at developers, systems administrators and any organisation that performs on-premise, remote, or hybrid computing.

Features

- Controls public and private clouds, containers, bare metal servers and more.
- Has fine grained controls for delegating access to team members.
- Enables cost and usage reporting across the whole infrastructure.
- Orchestrates repeatable deployments, and automates common responses.
- Enforces policies consistently, across any computing platform.

VirtEngine

VirtEngine is an open source CMP that can be used to build private or public clouds, which support IaaS, PaaS and SaaS. This Platform as a Service system allows customers to deploy applications in a few clicks. VirtEngine has a wide range of applications and a simple user interface for customers to self-serve their needs. It helps users build both public and private clouds within very little time, and supports infrastructure platforms and other storage devices. It is also very scalable and comes with automation tools that provide companies a competitive advantage. VirtEngine by DET.io is available as two different solutions for the public and private cloud. The public cloud allows users to build their own cloud and offer servers to customers. It is available as a mini edition as well as a complete solution. The private cloud is available as an open source and free solution as well as a powerful solution for enterprises that supports HA and other enterprise features.

Features

- Access control, demand and supply monitoring, cost management, multi-cloud management, one-click apps, and automatic launch.
- DNS support, self-healing, cloud-native, multi-locations, Docker containers, cloud virtual machines and migration tools.

openQRM

openQRM is a free and open source cloud computing management platform for managing heterogeneous data centre infrastructures. It provides a complete, automated workflow engine for all bare metal and VM deployment, as well as for all IT sub-systems, enabling professional management and monitoring of the data centre and cloud capacities. The openQRM

platform manages a data centre's infrastructure to build private, public and hybrid Infrastructure as a Service clouds. openQRM orchestrates storage, networks, virtualisation, monitoring and security implementation technologies to deploy multi-tier services as virtual machines on distributed infrastructures, combining both data centre resources and remote cloud resources, according to allocation policies.

openQRM provides a Web-based, open source data centre management and cloud platform with the help of which various internal and external technologies can be abstracted and grouped within a common management tool. This management system also takes care of provisioning, high availability and the monitoring of services offered. Instead of providing individual tools for individual tasks, such as configuration management and system monitoring, openQRM integrates proven open source management tools such as Nagios and Zabbix.

Architecture: The openQRM system architecture comprises three components -- data centre management and cloud platform, the plugin API, and the hybrid cloud connector.

The data centre management and cloud platform provides the basic functionality of openQRM, and uses the plugin API to communicate with the data centre's resources that are also installed on the local network (hypervisor, storage and network). openQRM comes with support for five virtualisation environments -- VMware ESX, Citrix XenServer, KVM, LXC and OpenVZ.

openQRM can handle LVM, iSCSI, NFS, ATA over Ethernet, SAN Boot and Tmpfs storage. For the network configuration, openQRM integrates critical network services such as DNS, DHCP, TFTP and Wake-on-LAN. The network manager included with the package helps administrators configure the network bridges required for these services. The hybrid cloud connector
