

# The Emergence of Edge Analytics in the IoT Ecosystem

Edge analytics involves processing, collecting and analysing data near its source so that not all of it is sent to the cloud. This is crucial when massive volumes of data are generated by numerous devices. It saves a lot of time and reduces latency.

**T**he exponential proliferation of IoT devices and IoT based platforms is leading to multiple complex scenarios. Such sudden growth and scalability need a lot of analytics to be done for better predictions and choices. IoT analytics will become more complex and challenging when the number of IoT devices grows even further. A good analytics system will become crucial for any IoT environment to succeed and be more robust.

Making any sense out of IoT data needs good and efficient analytics.

This may not always be Big Data (volume, velocity and variety of data). There are many other categories of analytics, like simple past event review, or more advanced analytics using historical data to make predictions about outcomes, etc.

## What is analytics?

Analytics (for IoT) is the science and art of trying to find matching patterns in the huge quantity of data (it could be Big Data, or otherwise) generated by connected and smart devices. In

layman's terms, this can be defined as simply as monitoring trends and finding any abnormalities.

Listed below are some of the well-known analytics methodologies or types:

- Descriptive analytics tells us what is happening
- Diagnostics analytics tells us why it happened
- Predictive analytics tells us what is likely to happen
- Prescriptive analytics tells us what should be done to prevent something from happening
