

Figure 4: CoAP

Figure 5: Constrained Application Protocol architecture

combination of 'Request/Response and Message'. We can also say it has two layers – 'Request/Response' and 'Message'.

Figure 5 clearly explains that CoAP architecture is based on the client server relationship, where...

- The client sends requests to the server.
- The server receives requests from the client and responds to them.

Figure 6: Extensible Messaging and Presence Protocol

Extensible Messaging and Presence Protocol (XMPP)

This protocol is used to exchange messages in real-time. It is used not only to communicate with others, but also to get information on the status of the user (away, offline, active). This protocol is widely used in real life, like in WhatsApp.

The Extensible Messaging and Presence Protocol should be used because:

- It is free, open and easy to understand. Hence, it is very popular.
- It has secured authentication, is extensible and flexible.

How XMPP works and its architecture: In the XMPP architecture, each client has a

unique name associated with it and communicates to other clients via the XMPP server. The XMPP client has either the same domain or a different one.

In Figure 6, the XMPP client belongs to the same domain in which one XMPP client sends the information to the XMPP server. The server translates it and conveys the information to another client.

Basically, this protocol is the backbone that provides universal connectivity between different endpoint protocols. **END** 🐧
