

Huawei unveils its own operating system, 'HarmonyOS'

Huawei has developed its own operating system, ending its reliance on Google's Android.

The Chinese tech giant has officially launched its new operating system, HarmonyOS, which will be known as Hongmeng in China.

The company said that the operating system, a microkernel-based distributed OS, can be used in everything from smartphones and smart speakers to wearables and in-vehicle systems, in order to create a shared ecosystem across devices.

But for now, Huawei plans to focus on smart screens. According to reports, the first HarmonyOS-powered devices will be a pair of smart TVs called the Honor Vision and Honor Vision Pro, which will go on sale in China soon.

The company also plans to release the operating system as an open source platform worldwide to encourage adoption.

HarmonyOS is part of Huawei's efforts to decrease its reliance on Google's Android operating system. Google suspended the company's Android licence back in May, following the US government's decision to put Huawei on the Entity List. (This list contains the names of non-US parties that are subject to specific licence requirements for the export, re-export, and/or in-country transfer of controlled items, ensuring that sensitive technologies do not get used in ways the US believes will harm its own interests.)

Although the company has indicated that the OS is ready to run on phones, it said that it plans to continue using Android for its own smartphones for the time being.

"Because we support Google's Android ecosystem, we will prioritise Android for smartphones. If we can't use Android, we can install HarmonyOS quickly," company sources said at Huawei's developers' conference in Dongguan.

The source also pointed out that HarmonyOS is "completely different from Android and iOS" because of its ability to scale across different kinds of devices.

ForgeRock releases open source IoT edge controller solution to secure device identities

US based digital identity management company, ForgeRock, has announced the immediate availability of its IoT edge controller, which provides consumer and industrial manufacturers the ability to deliver trusted identity at the device level.

In this way, 'things' can have the same identity capabilities as traditional (customer or employee) identities, the company said in a statement.

A complete end-to-end security solution for IoT deployments, the IoT edge controller runs on smart edge devices and provides the privacy, integrity and security required for devices to register as identities in the ForgeRock Identity Platform. This open source edge controller allows businesses to include digital identities as part of products and significantly accelerate time-to-market of new IoT solutions.

The ForgeRock IoT edge controller delivers identity-driven security by creating trusted identities, and ensuring the ongoing authenticity and authorisation of connected devices, their transactions and data streams.

Built using open standards, the IoT edge controller features contextual security, scales to meet IoT-level demands, and enables customers to optimise operating costs of IoT implementations.
