

recently announced the open source release of TensorWatch in a blog post.

“We like to think of TensorWatch as the Swiss Army knife of debugging tools with many advanced capabilities researchers and engineers will find helpful in their work,” the team wrote.

TensorWatch provides the interactive debugging of real-time training processes using either the composable UI in Jupyter Notebooks or the live shareable dashboards in Jupyter Lab.

In addition, since TensorWatch is a Python library, researchers can build their own custom UIs or use TensorWatch in the vast Python data science ecosystem. TensorWatch also supports several standard visualisation types, including bar charts, histograms, pie charts, as well as 3D variations.

With TensorWatch, the team also introduces lazy logging mode. “This mode doesn’t require explicit logging of all the information beforehand. Instead, you can have TensorWatch observe the variables. Since

observing is basically free, you can track as many variables as you like, including large models or entire batches during the training,” the team’s blog post stated.

Microsoft uses several open source libraries to enable many of these features, which include model graph visualisation, data exploration through dimensionality reduction, model statistics and several prediction explainers for convolution networks.

True to its word, Huawei releases source code of Ark compiler

Chinese tech giant Huawei has finally released the source code of its Android compiler. Earlier this year, Huawei unveiled the Ark compiler to make Android app compilation more fluent. By open sourcing the compiler,

Huawei wants to nurture the developer ecosystem, which can play a significant role in the growth of Huawei’s recently launched operating system (OS), HarmonyOS.

While the Chinese electronics maker did not disclose details, industry analysts believe that the company may be using the Ark compiler as the foundation of its own operating system.

According to Huawei, the Ark compiler can improve Android system operation fluency by 24 per cent, response speed by 44 per cent, and the smoothness of the third party application up to 60 per cent.

Launched in April this year, the Ark compiler is currently installed in Huawei P30, P30 Pro, Nova 5, Nova 5 Pro, Honor 20, 20 Pro, Honor View 20 and some other devices.

Further information on the Ark compiler is likely to be released during the Huawei Developer Conference 2019.
