

SSL Certificates: Make the Right Choice

Increasingly sophisticated techniques are being used to hack into data today. So it has become extremely important to use even better ways to protect your customers' data. SSL certification is one such way. This article looks at the different types of SSL certificates and how to choose one that suits your organisation.

SSL certificates are an apt solution for securing data in transit. They create an automated mechanism to encrypt the transfer of data between the server and browser (or site and visitor). This encryption can only be decrypted by the intended system. So it discourages hackers from stealing data, and offers complete security against transit attacks on it.

Along with securing communication, SSL certificates also build trust with customers and help you emerge as a credible business by

displaying virtual trust icons like a padlock, HTTPS prefix, and a green address bar. So let's learn about the major types of SSL certificates and how to choose the one that works best for you.

SSL certificate options: Similarities and differences

Let's first discuss the basic similarity all SSL certificates share. Regardless of their type, price and scope, every SSL certificate encrypts the to-and-fro communication between the site's

server and the Internet browser of your visitor.

The difference lies in the terms and conditions of the validation process and the number of domains/subdomains it covers, etc. Proceeding to purchase an SSL certificate without first reviewing your present and future needs may result in costly mistakes, and you may end up paying a hefty amount for advanced features that are irrelevant to your business. Or you may get tempted to buy a cheap certificate that isn't a perfect fit for your business needs.
