

Aqua Security acquires tfsec

Image Source: rawpixel.com

Aqua Security has announced the acquisition of tfsec, an open source security scanner for Infrastructure as Code (IaC). The acquisition brings an immediate integration of tfsec into Aqua Trivy, adding IaC security scanning capabilities, with additional Aqua platform integrations planned later this year. tfsec's co-founders Liam Galvin and Owen Rumney will join the Aqua team as cloud engineers, bringing deep experience in both software and open source.

Amir Jerbi, CTO and co-founder of Aqua Security, said, "tfsec is the known leader in Terraform code scanning, and we're thrilled to bring its capabilities and intelligence under Aqua's open source and commercial umbrella. Aqua is committed to investing in open source cloud security tools and to providing users a frictionless way to assimilate essential security capabilities into their cloud native applications, where they need them most."

Itay Shakury, director of open source at Aqua Security, said, "Aqua Trivy has become the industry standard for open source vulnerability scanning thanks to its simple user experience and rich functionality. Now, Trivy brings the same superior experience into Infrastructure as Code scanning to provide even more value to container and code scanning. By integrating tfsec and Trivy, our users can scan code repositories and container images for vulnerabilities and IaC configuration issues – all using a single tool that can integrate into their CI tool or even be used as a GitHub action."

While tfsec will remain a standalone project, in addition to its integration into Trivy, it will also be added to Aqua Security's suite of open source cloud security tools, including Tracee, Starboard, Kube-bench and Kube-hunter. With this portfolio, users can also perform penetration tests of Kubernetes clusters, integrate disparate Kubernetes security tools into an aggregate security data set that is available natively in Kubernetes, view runtime and forensics data for Linux, and more.

Developers have a strong influence over technology purchase decisions: IDC survey

An IDC survey has observed that developers are not only the architects and visionaries of digital transformation but also have end-to-end line of sight into the processes that govern the manufacture of digital solutions. Full-stack developers have proficiency in both the development of business logic and the management of data, as well as the development of rich frontend experiences that are consumed by end users.

IBM launches open source framework named CodeFlare

IBM has launched an open source framework called CodeFlare for simplifying the integration, scaling, and speeding up of complex multi-step analytics and machine learning pipelines on the hybrid multi-cloud. CodeFlare has been built on top of Ray on IBM Cloud Code Engine, which is an open source distributed computing framework for machine learning applications. The new open source framework is said to extend Ray's capabilities through the addition of specific elements for making scaling workflows easier.

IBM said that for creating a machine learning model, researchers and developers are currently required to first train and optimise it. The process is said to be simplified by CodeFlare by using a Python-based interface. The new framework's objective is to unify pipeline workflows across various platforms without the need for data scientists learning a new workflow language.

Data and machine learning analytics are proliferating into just about every industry, with tasks becoming ever more complex. Larger data sets and more systems designed for AI research are fantastic but as these workflows become more involved, researchers are spending more and more time configuring their setups than getting data science done.

CodeFlare pipelines run with ease on IBM Cloud Code Engine, which is the company's new serverless platform, and on Red Hat OpenShift too.
