

Cloud Management Using Apache CloudStack: An Overview

Clouds are pools of virtual resources, storage, applications and services that are managed by software so that on-demand resources can be accessed. Clouds provide the rules and cloud management carries them out. Today's IT infrastructure demands more control over dynamic and scalable computing environments, and for that strong cloud management is required. Apache CloudStack can help here.

Cloud management is defined as software and technologies designed for operating and monitoring applications, data and services residing in the cloud. It is a combination of software, automation, policies, government and people that determine exactly how cloud computing services will be made available.

Cloud management requires tons of tasks, starting from performance monitoring, security administration, auditing and management to overseeing and maintaining disaster recovery, as well as backup and contingency plans. As cloud computing grows over time and a wide range of public, private, hybrid

and even community clouds are adopted by enterprises, strong cloud management tools need to be deployed for managing cloud computing orientations.

Strong and effective cloud management lays a strong foundation for companies to attain the following organisational and technological goals.

- **Self-service:** This is concerned with the flexibility of operations in handling day-to-day tasks with regard to cloud accessibility, addition of new clouds, monitoring and auditing and, of course, resource management.
