

MariaDB can be used in any environment that the developer can think of. It can be queried with the help of almost all the popular querying languages.

MongoDB

Mongo DB is a leading NoSQL database. This document-oriented database stores structured data as JSON-like documents with dynamic schemas, due to which the integration of data in some kinds of applications

becomes significantly faster and easier. It has a powerful query language that allows you to filter and sort data by any field, no matter how deep-seated it may be within a document. It also supports aggregations and other modern use cases such as geo-based search, graph search, and text search.

CouchDB

CouchDB is an open source NoSQL document database. It collects and stores data in JSON documents that

you can access via the Web or query using JavaScript. With a schema-free data model, CouchDB simplifies record management.

CouchDB was launched in 2005. In 2008, it became an Apache Software Foundation project. Whether it is a general-purpose document store, enabling efficient data synchronisation, or adopting an 'offline first' mindset, CouchDB gives businesses the flexibility to create durable, reliable, and scalable infrastructures.
