

Intel acquires Ananki and the ONF dev team

With the acquisition of the Open Networking Foundation's (ONF) development team (which has been working on multiple projects spanning the mobile, broadband, and programmable networking sectors), and of Ananki, the 5G private networking software development company spun out of the ONF in September 2021, Intel has gained significant open source networking expertise in recent weeks. Intel hasn't made a public announcement regarding the deal with Ananki, and no financial specifics have been disclosed.

Ananki is an ONF spin-off that took the software stacks developed by multiple ONF projects – including Aether (connected edge cloud), SD-RAN, SD-Fabric, and SD-Core – and made them available as a SaaS to make “private 5G as easy to consume as Wi-Fi for enterprises.” The ONF development team was adopted by Intel as part of a broader reorganisation of the Foundation that saw it morph into a “more classic open source organisation” by putting its portfolio of open networking platforms into the open source community, including public 5G (SD-Core, SD-RAN), private 5G networks (Aether), software-defined broadband (SEBA/VOLTHA), and P4 programmable networks (SD-Fabric, PINS).

Guru Parulkar, the CEO of Ananki and ONF's former executive director, joined Intel's Network and Edge team as VP of software in April this year.

Spotify has joined a long list of organisations in establishing a dedicated open source program office (OSPO), which is supposed to bring formality and order to all its open source initiatives, connect OSS project goals with key business objectives, and manage licence and compliance issues.

Despite security issues, open source usage is on the rise

Despite vulnerabilities like Log4j, enterprise use of open source has not slowed down; however, faults have emphasised the need for a better knowledge of dependencies. Open source's image in the computer industry has come a long way. Even in the face of well-publicised open source flaws like Log4j, open source software continues to gain popularity in the workplace, displacing proprietary software.

It's usual for developers to pull in freely available code snippets or dependencies that have already been created, tested, and performed when using open source. This has the benefit of shortening the development life cycle because teams don't have to rewrite code that already exists.

According to Red Hat, IT directors expect their organisations' share of proprietary software to shrink from 45 per cent to 37 per cent over the next two years. Enterprise open source adoption is forecast to rise from 29 per cent to 34 per cent, while community-based open source adoption is expected to rise from 21 per cent to 24 per cent.

Oculus Link loads directly into SteamVR with OculusKiller

Oculus Link can be loaded directly into SteamVR with the use of an open source tool called OculusKiller, which disables Oculus Dash. Kaitlyn, a software engineer, created the program, which is available on GitHub. You might recognise the name OculusKiller – there's another tool on GitHub with the same name, but it's for a different purpose: forcibly killing Oculus services running on your PC.
