

Kaitlyn's OculusKiller is a technical term for an executable that substitutes the Oculus Dash executable with a simple SteamVR loader. The Oculus PC software must be active; however, the in-VR Oculus PC interface is no longer available.

Kaitlyn believes that removing the Oculus Dash will “significantly improve speed,” as it consumes “200 MB of memory + GPU, even when not in use.” There is one issue, however; there is no way to exit SteamVR from within VR, as it will simply relaunch itself when it shuts.

Samsung is now a member of the O-RAN Project's TOC

Samsung Electronics has been elected as an official member of the Technical Oversight Committee (TOC) for the O-RAN open source project, the O-RAN Software Community's main decision-making body. The company will play a crucial role in the O-RAN open source project's decision making for a

period that began in April 2022 and ends in 2023.

Samsung, together with 11 other corporations, has been elected as

an official member of the TOC, the O-RAN SC's top voting body, as a result of its pioneering work. Following the membership offer, JinGuk Jeong, vice president and head of the Advanced Solutions Team at Samsung Research's Advanced Communications Research Center, has commenced his term as the company's representative to the TOC.

Six global telecommunications operators — AT&T, China Mobile, Deutsche Telekom, Orange, NTT Docomo, and TIM — and six telecommunications equipment and component providers — Samsung Electronics, Ericsson, Nokia, Windriver, Radisys, and Viavi — make up the O-RAN SC TOC, which has twelve seats.

Calico CNI for Azure Kubernetes Service is now available

Calico Container Networking Interface (CNI) for Azure Kubernetes Service (AKS) is now available, according to Tigera, the creator and maintainer of Calico Open Source, the widely used container networking and security solution and foundation for zero-trust workload security. AKS users will now be able to leverage Calico Open Source as a CNI for robust and high-performing networking for their environments.

RISC-V chip built by Danish students uses open source tools

A RISC-V two core chip with open source software has been built by 12 students in Denmark. The chip is being made for free in the United States thanks to a partnership between Google and foundry Skywater. The students are taking a chip design course at Denmark Technical University (DTU), which is the first time the university has taught the subject using open source tools.

The European Chips Act, according to the university, is spurring the demand for additional chip designers in the region. Jrgen Kragh Jakobsen, an analogue chip designer at IC Works, suggested that the special course be created to pique young people's interest in chip design.

“We need innovation in this area. And the special course here is the first generation of some chip designers working with open source tools. We have not seen that before. And it will explode over the next few years,” said Jakobsen.

The open source tools are part of the Skywater 130nm Process Design Kit (PDK), which includes an open source RTL2GDS design stack dubbed openLANE developed by Efabless and licensed under the Apache 2.0 license. A standardised test harness is open and free to use, allowing verification results to be duplicated quickly and cheaply.
