

HarmonyOS: Helping Devices Collaborate with Each Other

All smart devices today run on operating systems that are different from each other. Integrating these devices so that they can communicate with each other to accomplish a particular task becomes a tough ask. HarmonyOS helps them collaborate, improving the overall user experience.

HarmonyOS is an operating system (OS) for all the smart devices out there. As its tagline “one as all, all as one” suggests, it is an OS capable of seamlessly running on multiple devices. It can be used in a single device to access multiple devices, which can then all function like a single device at the same time. Let us first understand why it was needed in the first place.

- IoT (Internet of Things) devices have seen substantial growth over the past few years along with the proliferation of smartphone devices. This is one of the reasons why an OS that integrates IoT devices harmoniously with smartphone devices is needed. HarmonyOS is an equally good standalone OS and has a high level of performance, low power consumption, as well as low audio latency.
- Operating systems are fragmented. The different operating systems available have been made by different vendors for various forms of devices such as mobile phones, tablets, and smart watches. That makes it difficult for them to integrate with each other.
- It gets hard for developers to build an application for different
