

aspose.app/gis/en/conversion/shapefile-to-kml.

Step 4: Select layers that can be superimposed to this Google satellite hybrid image (refer Figure 3).

Step 5: Open the data source manager vector file addition option from the menu.

Step 6: Provide the correct path to obtain the *.kml* file from the download location and add it.

Step 7: Open the concerned *.kml* file into the *Data Source Manager-Vector* mode and select the *Add* option (middle button on the right bottom). It should display the list of eligible files that can be added to it (refer Figure 4).

Step 8: Click *Add layers* (which you wish to include in the map to view).

Close the data source manager. You should be able to locate two files on the *Layers* window:

- The reef details file
- Google satellite hybrid image file

Remember to put the reef details in first position followed by the Google satellite hybrid image, else the reef details won't be visible at the desired locations.

```

Python Console
1 Python Console
2 Use iface to access QGIS API interface or Type help(iface) for more info
3 >>> layer = qgis.utils.iface.activeLayer()
4 >>> layer.id()
5 'inputnew_6740bb2e_0441_4af5_8dcf_305c5c4d8ca7'
6 >>> layer.featureCount()
7 18
8

```

Figure 7: A typical QGIS Python console

Zoom on to your region of interest or make sure you select only those reefs and islands that you wish to study. You should be able to identify specific locations that are in the Arabian Sea. They presently appear with a yellow background (see Figure 5).

You can access the properties with a right click on the reefs layer for other options.

Now, if you wish, you may alter the colour and the boundary of the symbols and change their representation.

A typical outline of the reefs located on specific islands is shown in Figure 6.

Moving on to the Python console

Python was first introduced in QGIS 0.9, and Python codes can be implemented in the QGIS environment using the following ways:

- Issue commands in the Python console within QGIS (the most popular choice and also widely implemented)
- Create and use plugins
- Automatically run Python code when QGIS starts
- Create processing algorithms
- Create functions for expressions in QGIS
- Create custom applications based on the QGIS API
