

CloudLinux Inc. launches KuberLogic

CloudLinux Inc. has launched its new open source project – KuberLogic, a new PaaS model platform for deploying, managing, and scaling software hosted on the Kubernetes cluster. The solution provides API, monitoring, backups, and integration with SSO right out of the box.

KuberLogic allows running managed databases and popular applications deployed on-premises or on any cloud platform. The new tool allows enterprise and service providers to look to cloud providers for managed database hosting and eliminate the administration effort by using its automated setup and management of complicated infrastructure software.

The tool includes fully automatic updates, backups, failovers, and recovery processes.

KuberLogic

KuberLogic allows any organisation to have a fully managed software infrastructure without vendor lockin to a cloud software-as-a-service (SaaS) solution or commitment of an in-house DevOps team. This platform enables clients to set up a scalable, self-healing PaaS on top of any Kubernetes cluster. This strategy gives the client complete control and the ability to embrace all the advantages of using open source solutions that can grow and adapt to the client's individual wants and needs.

“Today, developers want to be able to use highly diversified stacks of technologies in an on-demand, automated manner,” said Igor Seletskiy, CEO and founder of CloudLinux.

one's level of dev expertise. OSS Port connects projects to people and eases codebase onboarding with CodeSee Maps. Maps will be forever-free to the OSS community—a commitment made by CodeSee leaders in support of open source innovation,” read a company blog.

Maintainers can tag their projects to topics like ‘education’ and ‘social good’, so that contributors can search, select, and quickly onboard to the projects that matter most to them.

OSS Port allows maintainers to provide contribution best practices, support guidance, and interactive visual walkthroughs of their codebase using CodeSee Maps. It allows users to visualise how proposed changes will impact the larger codebase, with features highlighting dependencies and insights to guide your decisions.

Dell targets market for 5G networks built on open source hardware

Dell Technologies chief Michael Dell recently said that he sees an opportunity to play a key role in the global rollout of 5G networks with new technology that makes specialised equipment unnecessary.

The shift towards Open Radio Access Network (O-RAN) lets telecommunications carriers use software to run network functions on standardised computing hardware.

The technology has drawn interest from the US government because it will allow networks to be made with offerings from American firms such as Dell and Microsoft, rather than solely from industry-specific providers such as Nokia or China's Huawei Technologies Co Ltd.

In an interview, Dell said interest from the administration of former President Donald Trump in positioning the technology as a Western-led counterweight to Huawei has “fully carried over” to President Joe Biden's administration.

Dell makes the computing hardware that goes into the new style of networks and has already secured deals to help DISH Network Corp in the US, and Vodafone and Orange in Europe build 5G networks with the technology. Dell Technologies has announced software to help carriers manage the computers used in the new

networks, targeting release in November.

But most of the new O-RAN networks in Europe remain testbeds, and DISH is a 5G upstart building a network from scratch rather than an established player. Some telecommunications analysts believe

the new open technology will not be dominant for at least another generation of networks. Dell wants to speed up the shift by testing and hardening much of the new technology for broader use.

Falco adds AWS cloud security monitoring

Sysdig has announced the addition of cloud security monitoring functionality to the Falco open source software project. The new Amazon Web Services (AWS) CloudTrail plugin provides real-time detection of unexpected behaviour and configuration changes, intrusions, and data theft in AWS cloud services using Falco rules.
