

The Falco community developed this extension with Sysdig based on a new plugin framework that allows anyone to extend Falco to capture data from additional sources beyond Linux system calls and Kubernetes audit logs. As organisations manage critical data across multiple clouds, they need consistent threat detection across their distributed environments. Additional plugins will allow organisations to use a consistent threat detection language and close

security gaps by using consistent policies for workloads and infrastructure. In addition, more than 20 new out-of-the-box policies supporting compliance frameworks were released, the company said.

Today,

security teams are forced to export AWS CloudTrail logs into a data lake or security information and event management (SIEM) for processing, and then search for threats and changes to configurations that can indicate a risk. This approach adds delay in identifying risks, as well as cost and complexity.

Falco inspects cloud logs using a streaming approach, applying the rules to the logs in real-time and immediately alerting on issues, without the need to make an additional copy of the data. This approach complements static cloud security posture management by continually checking for unexpected changes to configurations and permissions that can increase risk. In addition, it acts as a modern intrusion detection system (IDS), detecting threats based on unusual behaviour that can indicate a threat.

Deepfence announces open source availability of 'ThreatMapper'

Deepfence, a security observability provider, has announced open source availability of ThreatMapper, an offering that automatically scans, maps and ranks application vulnerabilities across serverless, Kubernetes, container and multi-cloud environments.

ThreatMapper is an open source platform for scanning runtime environments for software supply chain vulnerabilities and contextualising threats to help organisations determine which to address and when. The comprehensive suite of its capabilities and features is available on GitHub. ThreatMapper complements an organisation's existing initiatives to "shift left" by scanning applications and infrastructure post-deployment, catching emerging threats and scanning both first-party and third-party applications and components.

For enterprises looking for a deeper runtime detection and protection, Deepfence offers a commercial solution named ThreatStryker. ThreatStryker builds on the attack surface measured by ThreatMapper, and gathers rich runtime signals using cloud native deep packet inspection (DPI) to give visibility at runtime. ThreatStryker then correlates these runtime signals with measured attack surface and deploys fine-grained, targeted remediation to prevent the spread of threats and stop attackers in their tracks, all this without proxies, intrusive agents or any inline components.

TriggerMesh open sources cloud native integration platform

TriggerMesh, a cloud native integration platform provider, has announced the launch of the TriggerMesh integration platform as an open source project for building event-driven architecture available under the Apache Software License 2.0.

TriggerMesh is said to simplify and accelerate connecting applications and data across multiple clouds and on-premise data centres. Its approach to integration is very similar to the way infrastructure as code solutions such as Ansible, Chef, HashiCorp, and Puppet use to deploy infrastructure by DevOps teams. The TriggerMesh free and open source platform allows cloud operators and DevOps practitioners to deploy integrations as codeTM, which accelerates time to value and improves flexibility compared with typical integration platform-as-a-service (PaaS) solutions.

TriggerMesh's platform takes an event-driven approach to integration, consuming messages from various sources (e.g., AWS SQS, Google Storage, Azure Activity Logs), filtering and transforming them, combining processing capabilities with serverless functions and connecting with message sinks (e.g., Elasticsearch, AWS S3, Apache Kafka).

Commercially, TriggerMesh provides support and services as well as a graphical user interface that offers a visual integration editor, enterprise authentication and authorisation with organisational support, and the capability to develop custom integration components.
