

Cube Dev announces availability of Cube Cloud

Cube Dev, the open source company behind Cube.js, has announced the general availability of Cube Cloud, a hosted version of the company's popular open source Cube.js analytics API.

With Cube Cloud, companies can build data applications like metrics dashboards and analytics features that consume data from their cloud data

warehouse—without building or hosting any of the complex technologies required to make this possible.

Cube Cloud connects to a company's SQL data sources and builds an API backend to serve this data to an application. This makes it easy for developers

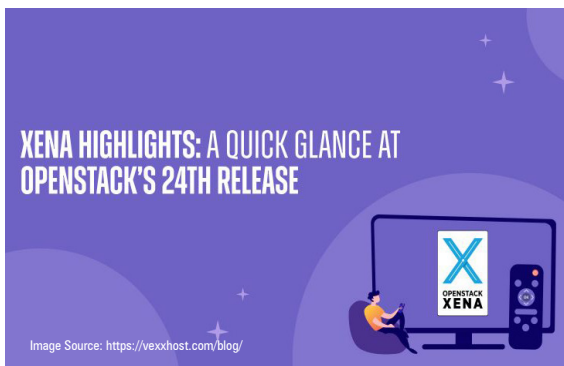

to build applications with the visualisation libraries and front-end code tools of their choice. The service leverages all of the features of the open source Cube offering including SQL modelling, data schema, access control, a querying API, and caching and acceleration.

Prior to Cube Cloud, developers used Cube technology by provisioning their own computing resources and using either npm or Docker to install the open source Cube.js software platform. In that case, a business would be responsible for monitoring server performance and provisioning additional cluster servers as their consumption increased.

With Cube Cloud, developers simply select the Google Cloud Platform or Amazon Web Services region where they want to deploy Cube Cloud and connect it to their data sources. As more data is consumed or an application attracts more concurrent users, Cube Cloud can automatically scale to provide additional computing resources.

OpenStack Xena is live with improved integrations and new features

The OpenStack community has released Xena, the 24th version of open source cloud infrastructure software. Highlights of the Xena release include support for

new hardware features, improved integration among components, and reduction of technical debt to maintain OpenStack's stable and reliable core.

OpenStack is one of the most active open source projects in the world, supported by a vibrant and engaged

community of developers globally. Over the span of just 25 weeks, almost 15,000 changes authored by over 680 contributors from over 125 different organisations were included in the Xena release.

DataStax announces availability of K8ssandra on VMware Marketplace

DataStax has announced that K8ssandra, an open source distribution of Apache Cassandra on Kubernetes, is available on the VMware Marketplace.

VMware Marketplace enables customers to discover and deploy compatible, validated third-party solutions to VMware environments. Once validated, partners can easily publish their solutions for VMware customers across platforms. Customers will be able to access these third-party partner solutions directly from their cloud environments, while also being able to experience the convenience of features such as notifications, reporting, and analytics.

K8SSANDRA

K8ssandra combines the flexible, cloud-native benefits of Kubernetes together with the global scale of Cassandra — the NoSQL database used by leading enterprises including Apple, Instagram, Netflix, Sky, Spotify, TikTok, Uber, and Yelp. It is a complete operational data platform for Kubernetes including APIs, monitoring, and backups, providing database administrators (DBAs) and site reliability engineers (SREs) elastic scale for data on Kubernetes, the company said in a release.

"K8ssandra brings data to the edge to reduce latency and provide inherent high availability with the most scalable and stable multi-cloud database, all with a universal control plane for full operational life cycle management in a single platform," said Joshua Norrid, senior technical director of value engineering for DataStax.
