

Figure 2: Technology disruption and rise of open source

End-to-end open source software collaboration use cases

Joshipura points to some interesting use cases for the core and edge.

ORAN use cases include the slicing and the disaggregation that come with open RAN. In Kubernetes, it's the multi-cloud hybrid layer below with the standard compliance. ONAP is the largest and the most important. It goes through 5G network slicing and all the use cases for telecom. "This is really

the fundamental platform; 10 plus million lines of code are at the heart of network automation, and network automation is a must for 5G," he says.

As a global community, ONAP has matured and is now one of the most important projects enabling end-to-end systems.

Edge use cases driving open source projects

In case of intermittent connectivity, the user needs an on-premise

framework — that's Eve or edge virtualisation. EdgeXFoundry by far is the largest framework for IoT.

LF Networking may now be working on about 10 projects — Magma cloud native computing foundation, Kubernetes, or a software community. "We are taking these communities and doing an open 5G Super Blueprint integration," says Joshipura.

How does all of it come together?

The 5G Super Blueprint comes pre-baked, and very little integration and support is needed by the community or its vendors. So instead of multiple vendors doing things in different ways, it is now done in the community, and then the vendor can provide innovation and differentiation on top.

5G will modernise today's energy grid with awareness monitoring across distribution systems.

It will roll out in three phases: 5G core + MEC phase, 5G E2E + MEC phase and 5G + Slicing + O-RAN-SC + MEC phase.
