

The first step is intelligence gathering. It is also known as probing. At this stage, the team is relatively small and may have only three or four cross-functional experts. The goal is not to take any action, only watch and learn. Probe, if necessary, to gather more intelligence.

Once the information is gathered after probing, it is converted to wisdom or insights, as they would call it in data-analytics parlance. And they start gathering actionable intelligence. Something that can be used to take significant action. Something that is more reliable and can guarantee success. The team often uses SWOT analysis to direct their efforts and utilise resources efficiently.

Until this point, the core team is still the same. However, it now starts to deploy more members on a need basis. This way, the functional team grows slightly. At this stage, typically, seven to ten members may get involved in those activities.

And as soon as the intelligence is available, it is action time. That is when the overall command is handed over to someone who will see through the whole mission. The mission heads are empowered to choose their teams. They are also empowered to define their strategy for maximum success guarantee.

The usual approach is to start with small battles and gain a foothold. Later these small battles morph into several breakouts. These breakouts then may (or may not) result in a full-fledged war.

Regardless of all the above, nearly every mission has a high reliance on composite units. Composite units are competent teams with all the resources necessary for their operation. In a way, they are small but self-sufficient teams.

How it translates to business?

Now let us look at how does it translate in the corporate sector? If we were to learn anything from defense here, let us learn how it operates with minimal resources, speed, and agility.

If your company's mission is to explore new markets or launch new products, it is good to use a small team for scouting. You may have seen that startups usually have two co-founders, and it works quite well for them.

Once things start taking shape, this small team can get more hands to help and generate actionable insights. When I worked with LG Electronics, we extensively used the concept of the TDR teams, that is, tear down reengineering teams for such projects. These teams functioned like composite units, completely self-sufficient to execute small projects on their own, from start to end.

Once you get more comfortable with the outcomes, you can align all the necessary resources and commission a full project. I strongly believe that you must master the art of experimentation to master the art of the future of work! Special-purpose teams can make experimentation feasible.

But remember that small, focused project teams need cross-functional members. They need autonomy. Some latitude to operate. Proper access to the infrastructure and resources. They also need access to decision-makers, and there has to be the shortest path to make that happen. Let us say that they are corporate equivalents of a composite unit.

Why should you try it?

Now the question is, why should you try it? You see, it is extremely critical

to have the ability to change directions quickly and reorganise in the time of disruption. It is a must-have. Plus, adaptability is a crucial trait when you operate in a highly volatile, uncertain world. And you can improve all this significantly when you have resizable and modular teams.

Special-purpose teams can help you to innovate. They can help you improve outcomes. And while doing all that, they will also help increase your agility by several notches. Imbibing startup culture is something many businesses dream of. Having special-purpose teams in your organisation will enable you to do that.

As I mentioned in an earlier article, more and more organisations now have at least three different generations in their employee mix. So, these types of new team structures and management principles are becoming a necessity. And none of it will work until you take intentional steps.

I would invite you to test these proven strategies in your domain, in your business. Do it on a small scale. Try them out. See what works for you and what does not.

Make the future of work, work for you!  **END**
